LIBRARY, JAIPUR.

THE LANCET.

Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, ~~Public Health~~, and News.

IN TWO VOLUMES ANNUALLY.

VOL. CCVII.

VOL. II. FOR 1924.

ONE HUNDRED AND SECOND YEAR.

EDITED BY

SIR SQUIRE SPRIGGE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE.

LONDON
RINTED BY HAZELL, WATSON & VINEY LD., 52, LONG ACRE, W.C. 2, AND PUBLISHED BY THE PROPRIETORS,
AT THE OFFICES OF "THE LANCET," No. 423, STRAND, AND No. 1, BEDFORD STREET, STRAND,
MCMXXIV.

INDEX TO VOLUME II., 1924.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.)=Annotation, (C.)=Correspondence, (C.M.P.)=Conduct of Medical Practice, (I. and A.)=Inventions and Appliances, (L.A.)=Leading Article, (M.L.)=Medico-legal, (M.T.T.)=Modern Technique in Treatment, (O.)=Obituary, (P.I.)=Parliamentary Intelligence, (R.)=Review, and (R. and A.R.)=Reports and Analytical Records.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abderhalden, Emil (ed.), Handbuch der biologischen Arbeitsmethoden (R.), 175

Abdominal illness in children, acute, diagnosis of (G. Bryan), 737

Aberdeen, S.M.O.'s report, 1148

Abraham, J. Johnston, lectures on gonorrhœa in women and children (R.), 496

Abrams, Albert, 803; electronic reactions of (L. A.), 866

Accident prevention, 719

Accidents, psychopathology of (L. A.), 812; street, medical attendance in, 360

Acclimatisation in the tropics (A.), 32

Accommodation and refraction, errors of, and their treatment (Ernest Clarke), 5th ed. (R.), 1290

Actinomycosis, case of (A. I. G. McLaughlin and D. S. Page), 114

Addison's anæmia (Robert Campbell oration, Belfast), 1196; diagnosis of, by new optical method (Adrianus Pijper), 367; (C.), 524

Adler, Alfred, individual psychology (R.), 1182

Adrenalin as an analgesic (A.), 561; treatment of Stokes-Adams attacks (J. Parkinson and C. W. C. Bain), 311

Advertising, indirect, discussion on, at B.M.A. annual meeting, 244; report of Ethical Committee of B.M.A., 246

Advertising, oblique (A.), 226

Aeroplane crashes, prevention of (A.), 31

Africa, Central, days gone by in (J. E. Hine) (R.), 1344

Aikins, Dr. W. H. B. (O.), 939

Air-embolism in obstetrics (A.), 561

Alastrim and variola (Ricardo Jorge), 1317, 1366

Alcohol: Liquor (Popular Control) Bill, debate on, 47

Alcoholism and exhibitionism, 373; chronic, in Roumanian hospitals, 288

Alcoholuria, endogenous (A.), 974

Alexandra Day collection for charities, 732

Alimentation naturelle chez l'enfant (Dr. Monteunis) (R.), 754

Alkalæmia, 378

Alkali reserve of blood in coliform infections of kidney (E. H. Lepper and E. M. Martland), 485

Alkaloids, plant (T. A. Henry), 2nd ed. (R.), 916

Allen, Dr. V. F. (O.), 579

Allenburys diet for adults (R. and A.R.), 916

Alocol (R. and A.R.), 326

Alopecia, treatment of, 33; areata, lupus erythematosus and (M. G. Hannay), 1119; (C.), 1260

Alpine climate, post-graduate work on (A.), 181

"Alvus adstricta," 736

Amalgams: physiological incompatibilities in dental surgery (vol. i.) (U. Reinecke) (R.), 323

Ambriodin Centaur (R. and A.R.), 498

Ambulance, College of, and Col. Parkinson, 530

Ambulance Service, London, Fire Brigade and, 94

America, anæsthetics in (Z. Mennell), 411; (A.), 382; and England, post-graduate entente between, 1262; (A.), 1298

American Medical Association, 75th session, 135

American medical men, visit of, in 1925, 146; war services (A.), 332

American Public Health Association, annual meeting, 1036

American Social Hygienic Conference, 837

Ammonia and chlorine in water disinfection (A.), 384; (C.), 577

Amputations (N. T. Kirk) (R.), 914

Amsler, A. M., Beaumont, D. C., and Atlee, W., epidemic pleurisy, 492

Anæmia, Addison's, see Addison's anæmia; Gaucher's, case of (N. H. Schuster), 170

Anæmia, pernicious, see Addison's anæmia; thrombopenic, and splenectomy (A.), 229

Anæsthesia, blood reactions in (A.), 1245; for short operations in children (O. S. Thompson), 63; science and art of (W. Webster), (R.), 24; splanchnic (A.), 30; (A.), 347, and see Analgesia, splanchnic

Anæsthetic apparatus, universal (C.), 526; (C.), 578

Anæsthetics, comparative (A.), 382; in America, recent experiences of (Z. Mennell), 411; (A.), 382; in animal operations (A.), 1188

Analgesia, spinal (C.), 45; (C.), 90; splanchnic (O. S. Hillman), 9; (A.), 30; (A.), 1347, and see Anæsthesia, splanchnic

Anaphylactic phenomena after diphtheria antitoxin (N. S. R. Lorraine), 1010

Anaphylaxie, le problème de l' (A. Lumière) (R.), 24

Anaphylaxis and sensitisation (R. C. Low) (R.), 1237; in relation to migraine, 2; wheat reaction in relation to, 279; thermal, 306

Anatomie, Vergleichende, Vorlesungen über: Ernährungsorgane (O. Bütschli) (R.), 1022

Anderson, A. J. (O.), 1041

Aneurysm, aortic, case of (C. B. Pasley), 906; of splenic artery (A.), 976

Angina pectoris, surgical treatment, critique of (Sir James Mackenzie), 695; treatment of (J. Hay) (M.T.T.), 978

Animal operations, anæsthetics in (A.), 1188

Animals, dietary for (A.), 123; domestic, fertility, and sterility in (A.), 386; maintenance rations of (R. G. Linton), 130

Ankylostomiasis in the Argentine (A.), 331

Anson, Harold, discussion of the religious element in physical health (R.), 324

Antenatal care, discussion on, 388; death, prevention of, 66

Anthelmintics (L.A.), 124; (C.), 577; and their nomenclature (C.), 248

Anthrax, clinical features of, 293; Geneva International Labour Conference on, 250; in New York, 934

Antigens, heterologous, effect of, in relation to diagnosis of enteric (A. B. Rosher), 110

Anti-goitre campaign, a successful (L.A.), 611

Antimony tartrate in bilharzia (C.), 831

Antipneumococcal serum in lobar pneumonia (A. I. G. McLaughlin), 699

Anxiety states, treatment of (M. Culpin) (M.T.T.), 670

Appendicitis, hepatic abscess complicating (E. G. Slesinger), 19; in children, 738; unusual referred pain in (Sir B. Bruce-Porter), 495

Appendix abscess, torsion of omentum simulating (M. W. Bulman), 116

Appointments, weekly lists of, 51, 98, 147, 199, 253, 304, 358, 410, 479, 529, 580, 631, 682, 733, 787, 839, 890, 942, 995, 1045, 1103, 1157, 1212, 1264, 1316, 1365

Arc lamp, new sun-ray (I. and A.), 1106

Argentine, ankylostomiasis in the (A.), 331

Armstrong, E. Frankland, the simple carbohydrates and the glucosides, 4th ed. (R.), 601

Army in 1921, health of the, 716; and see Services, the

Arris and Gale lecture on diseases of gall-bladder in relation to functions of stomach and pancreas (H. E. Griffiths), 203

Arsenic in food wrappers in Salford, 630

Arthritis, acute, of hip, 350; deformans of large joints, operative treatment of, 350; infective, incidence of heart lesions in (T. W. Froggatt), 116; influenzal (D. Nabarro and J. F. H. Stallman), 743

Artificial limbs (A.), 27, 100; Anglesey (I. and A.), 634; sports prize-winners with, 410

Artificial pneumothorax (L. S. T. Burrell), 167; (A.), 179; criteria for (R. C. Wingfield and G. S. Wilson), 163; selective collapse in (C.), 351; (C.), 524

Artificial respiration, improved method (E. Seaborn), 148 ; (C.), 256
Asklepios, cult of, 359
Assistants, medical (J. Neal) (C.M.P.), 863
Association of Certificated Blind Masseurs, annual meeting, 198 ; report, 240
Assurance medical practice, some problems of, 1047

Social services in hospitals (A.), 280

SOCIETIES, MEDICAL.

Aberdeen Medico-Chirurgical Society.—Annual meeting, 1196—Exhibition of cases and specimens, 1070—Tumours of breast, 1035

Assurance Medical Society.—Presidential address, 1047

Brighton and Sussex Medico-Chirurgical Society.—X ray therapy, deep, 1017

Cardiff Medical Society.—Present-day health tendencies in Cardiff, 909

Chelsea Clinical Society.—Dinner, 681

Child-Study Society.—Lecture, 993

Durham University Medical Graduates' Association.—Election of officers, 46

Edinburgh Medico-Chirurgical Society.—Anti-pneumococcal immunity, 1288—Bile-passages, surgery of, 1287—Cataract, senile, intracapsular extraction of, 1125—Exhibition of cases, 173, 1126, 1178, 1288—Meeting, 1036—Ringworm and favus, immunity and sensitisation in, 1125—Visceroptosis, discussion on, 172

Edinburgh Obstetrical Society.—Antenatal, intranatal, and neonatal death, prevention of, 66—Exhibition of cases and specimens, 67

Glasgow Royal Medico-Chirurgical Society, 824

Harveian Society of London.—Clinical meeting, 786—Gift to, 1101—Insurance Act, National, future position of consultants under, 1283—Meeting, 993, 1067

Hunterian Society.—Dinner meeting, discussion on headache, 1285—The medical witness, 1065—Meeting of, 856, 1043

Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded.—Annual meeting, 99

Liverpool Medical Institution.—Arterio-sclerosis and the fundus oculi, 1127—Borderline cases, 1127—Cancer, discussion on, 1340—Empyema, treatment of, 1016—Encephalitis lethargica, 968—Meeting of, 888

London Association of the Medical Women's Federation.—Gonorrhœa, complications of, 1062—Micturition, frequency of, in women, 1339—Meeting of, 859, 1192

London Dermatological Society.—Meeting, 858

Manchester Medical Society.—Backache in women, chronic, 1286—Meeting of, 732

Manchester Pathological Society.—Streptococci in relation to human disease, 1124

Medical Officers of Schools Association, 681, 864, 1043

Medical Society of London.—Encephalitis lethargica, 1015—Gangrene, senile, treatment of, 1122—Insulin in treatment of diabetes, 1234—Lloyd Roberts lecture, 993—Syllabus, 731

Medical Society for Study of Venereal Diseases.—Exhibition of cases and specimens, 1177

Medical Women's International Association.—Forthcoming meeting, 94

Medico-Legal Society.—Dinner, 1313—Hanging as a humane method of execution, 997—Strychnine, fatal dose of, 997

Medico-Psychological Association.—Meeting, 993

National Association for the Prevention of Tuberculosis.—Annual conference, [illegible]

Newport Medical Society.—Meeting, 1124

North of England Obstetrical and Gynæcological Society.—Displacements of uterus, treatment of mobile backward, 964, 1235

Pathological Society of Great Britain and Ireland.—Meeting, 171

Rontgen Society.—Meeting, 888, 1162, 1351

Rontgen Society and Royal Society of Medicine.—Radiology, influence of, on criteria of disease, 119

Royal Academy of Medicine in Ireland.—Carcinoma of rectum, 1126—Corpus luteum, mammalian, 1341 — Encephalitis lethargica, sequelæ of, 1180

Royal Medical Society of Edinburgh.—Inaugural address, 931

Royal Society of Medicine.—Anæsthetics in America, 411—Anastomosis of facial and recurrent laryngeal nerves with others, 21—Annual clinical meeting, 117—Annual dinner, 871, 1194—Bakers' eczema, 859—Cancer cells in vitro, 1122—Cancer, increased and diminished resistance to induction of, 1122—Cavernous atrophy, relation of, to glaucoma, 1120—Ciliated epithelium in sinusitis, 20—Congress of Sections of Laryngology and Otology, 20—Cures, universal, ancient and modern, 802—Diathermy for pharyngeal cancer, 20—Ear and throat defects of elementary school-child, 20—Exhibition of cases and specimens, 1122, 1233, 1338—Eye positions, compensatory, 20—Hæmorrhoids, treatment of, by injection, discussion on, 117—Kidney, so-called myelin, 21—Kidneys, polycystic, discussion on, 22—Larynx, chondromata and chondro-osteomata of, 20—Larynx, ecchondrosis of, 20—Meningitis, non-tuberculous, 1281—Naso-pharynx, malignant disease of, 20—Nystagmus, miners', 1120—Pharyngeal cancer, diathermy for, 20—Pharynx, tortuosity of internal carotid in relation to, 20—Pruritus ani, 117—Puerperal sepsis, notification of, 817, 1011—Puerperal septicæmia in cattle, 1176—Rectum, cancer of, discussion on, 117—Rectum, prolapse of, 117—Rhinitis, atrophic, displacement of antro-nasal wall in treatment of, 20—Sacro-iliac disease, 1232—Scarlet fever and measles, otological and rhinological problems in, 21—Social evening, 669—Surgical section, presidential address, 961—Throat and ear defects of elementary school-child, 20—Thyroid gland, diagnosis of malignant disease of, 1231—Tints and their values, 801—Vertigo in relation to otolith and neck reflexes, 20—Vestibular function, experimental basis for theories of, 20

Royal Society of Medicine and Rontgen Society.—Radiology, influence of: on criteria of disease, 119

Royal Society of Tropical Medicine and Hygiene.—Malaria control, 962

Royal Statistical Society.—Meeting, 993

Society of Apothecaries of London.—Dinner to Dominions representatives, 95—Election of Dr. A. D. Brenchley as Master, 458—Pass-lists, 303, 528, 993, 1155

Society for Constructive Birth Control and Racial Progress.—Meeting, 1156

Society of Medical Officers of Health.—Annual dinner, 731—Meeting of, 94

Society of Members of the Royal College of Surgeons of England, 1043

Society for Prevention of Venereal Disease.—Annual meeting, 46; (A.), 74

Society for Study of Inebriety.—Meeting, 777, 857

South African Institute for Medical Research, 1044

Tropical Disease Prevention Association, 195

Tuberculosis Society.—Meeting, 1043, 1313

Ulster Medical Society.—Meeting, 1071

University College Hospital Medical Society.—Opening meeting, 749

West Kent Medico-Chirurgical Society.—Meeting, 993—Purvis oration, 1236

Yorkshire Tuberculosis Society.—Lecture, 772

Sodium morrhuate in the treatment of tuberculosis (John Hume), 162
Somerset, M.O.H.'s report, 1255
Soothill, V. F., injuries about the elbow-joint, 649
Sourds-Muets, les (G. de Parrel and Mme. Georges Lamarque) (R.), 1022
South Shields, M.O.H.'s annual report, 399
South-Western Asylums Research Institute, annual report, 137
Southgate, H. W., case of osteitis fibrosa, 1172
Southport, M.O.H.'s report from, 42
Spanish doctors' visit to London, 147
Spas in transition, the (C.), 884
Spearman, C. E., current views on individual differences of ability, 840
Spectacles for shooting (A.), 75
Speech in nervous diseases, 236
Speech, stomach, after laryngectomy, 237
Spenborough, M.O.H.'s report, 567
Spencer, Herbert R., renaissance of midwifery (Lloyd Roberts lecture), 1049
Sphygmography, a new method of (A.), 712
Spinal analgesia (C.), 45, 90
Spinal cord and cauda equina, injuries of (A.), 922
Spinal fracture, recovery from (A.), 667
Spinal rotation, apparatus for measuring (I. and A.), 1024
Spiritual healing (L.A.), 917; (C.), 990; discussion of the religious element in physical health (H. Anson) (R.), 324

THE
Savill Lecture
of the West End Hospital for Nervous Diseases
ON
MIGRAINE.

Delivered at the Royal Society of Medicine on July 3rd, 1924,

BY ARTHUR F. HURST, M.A., M.D. OXF., F.R.C.P.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

Thomas Dixon Savill wrote his admirable work on "Clinical Medicine" as a kind of protest against the tendency in modern text-books to bury the essential clincial features of disease under a mass of pathological speculation. It is therefore appropriate that in choosing the subject of migraine I have been led to do so by a desire to show how little scientific foundation there is for the greater part of the biochemical miasma in which the condition has in recent years become enshrouded, and to emphasise a few basic clinical facts, the realisation of which makes it possible to give complete, or almost complete, relief to a large majority of sufferers from migraine.

So far as the clinical picture of typical migraine is concerned, the main features were well recognised several hundred years ago. Aretæus of Cappadocia, in the second century A.D., was the first to distinguish migraine from other forms of headache by drawing attention to its unilateral and paroxysmal character. Cælius Aurelianus (400 A.D.) described some of the visual symptoms and Alexander Trallianus (600 A.D.) the disturbances in gastric function, but it was not until 1725 that Vater drew attention to the characteristic hemianopia, and 50 years later that Mirabeau, whilst in prison at Vincennes, wrote the first of the long series of graphic descriptions of the visual phenomena, for which the medical profession is indebted to lay victims of migraine. Dr. Edward Liveing, later the distinguished librarian of the Royal College of Physicians of London, collected all that was known of migraine in a remarkable volume published in 1872, and in the 50 years which have elapsed since then very little of importance has been added to our knowledge of its symptoms.

PATHOGENESIS.

I believe that there are two essential factors in the pathogenesis of migraine—one central, the other peripheral. The first is a constitutional and usually inherited predisposition. It does not depend upon any obvious structural abnormality of the brain, but upon a functional abnormality, something of the same nature as the functional abnormalities of the brain which are the essential factors in the pathogenesis of epilepsy and of asthma. Indeed, there appears to be a definite relationship between the functional abnormality underlying these three conditions, as they not infrequently coexist in the same family, and occasionally even in the same individual.

THE MIGRAINE STORM-CENTRE.

No satisfactory theory has ever been advanced as to the nature of the constitutional element in migraine, any more than it has been in epilepsy or asthma. Fifty years ago Liveing in his book "On Megrim and Sick-Headache," which is now, as it was then, the standard work on the subject, suggested that an attack of migraine should be regarded as a kind of "nerve-storm." The term is a useful one, even if it conveys no precise scientific meaning. For I do not think it is possible in the present state of our knowledge to do more than express the belief that migraine, epilepsy, and asthma depend upon a constitutional tendency of certain parts of the brain to become storm-centres under certain conditions. They only differ in the part of the brain concerned. In asthma it is obviously the part of the vagal nucleus which controls the constrictor and secretory fibres of the bronchi that is at fault. In epilepsy it is cortical, or, if more deeply seated, it is an area from which impulses to the cortex are discharged during an attack. The phenomena of migraine concern so many parts of the body that the cerebral localisation of the storm-centre upon which it depends is very difficult to define. The typical visual phenomena are due to stimulation followed by paralysis of an area in the occipital cortex; the rare aphasia and disturbances in the sensory and motor functions of the limbs are also no doubt cortical; the gastric and vasomotor symptoms must depend upon disturbances in the sympathetic nervous system, whilst the origin of the headache remains a complete mystery. Perhaps the storm-centre is somewhere at the base of the brain, from which impulses pass successively to the different parts concerned. This would explain why the exact order of events varies in different individuals, but remains fairly constant in each patient, and why in the same individual attacks vary greatly in the relative prominence of the successive phenomena, all of which do not necessarily recur in every attack.

About 15 years ago I first defined asthma as a condition in which spasm, excessive secretion, and congestion occur in the bronchi as a result of paroxysmal discharges from an abnormally irritable centre in the medulla brought about by chemical, psychical, and peripheral stimuli, and I have seen no reason to modify this conception of the disease as a result of increased experience. The abnormally irritable centre is the only constant factor. The same is perhaps true in epilepsy, as attacks may certainly be brought about by chemical, reflex, and psychical stimuli, though in the majority of attacks it is impossible to recognise the nature of the exciting cause. In migraine a biochemical factor has frequently been suggested, though there is little agreement as to its nature. Nobody, so far as I know, has ever regarded migraine as a psychoneurosis, though expectation is an occasional factor in many individuals subject to migraine. Various peripheral causes have been regarded as playing a part in the pathogenesis of migraine, and my own experience points to an ocular origin as of fundamental importance in a large majority, if not in all, cases. These various factors must now be considered in greater detail.

I. BIOCHEMICAL FACTORS.

A perusal of the recent literature on migraine leaves the impression that most authorities hope to find a way of salvation in modern biochemical research. There is much talk about toxic idiopathies and how they may be discovered by cutaneous reactions, and in this connexion the close relationship of migraine to asthma is regarded as a hopeful sign. Migraine is also one of the many conditions which have been regarded during the last few years as due to disturbances in the glands of internal secretion. Intestinal toxæmia following stasis in the ileum or the colon has become a widely accepted explanation of migraine, and attempts have been made to cure the condition by such heroic measures as the division of adhesions, short-circuiting operations, and even colectomy. More recently the liver has been incriminated, especially by French physicians, and now that a distinguished surgeon recommends splenectomy for recurrent biliary infection, we may expect the spleen to be added to the already somewhat bewildering list of organs in which the migraine-producing poison may arise.

It is interesting to note that most of these theories are nothing more than revivals in modern dress of the ancient humoral conception of disease. Thirteen hundred years ago Alexander Trallianus ascribed migraine to a superfluity of bilious humour, for which he recommended "aloes and scammony and other drugs which purge off bile without heating much."

chronic intestinal stasis, and the patients were wearing uncomfortable abdominal supports and dosing themselves with aperients, and many had had courses of Plombières douching. But both diagnoses had been made without bearing in mind how great are the normal variations. A pelvic cæcum and a greater curvature and transverse colon below the belt are, like a movable kidney, no more signs of disease than a crooked nose. They are frequently found in the healthy and vigorous, and the kinks and secondary adhesions, to which they are sometimes said to give rise, are almost always figments of the imagination. Many of the severest cases of intestinal toxæmia I have seen were in people who were poisoning themselves with aperients and with the toxins produced and absorbed in excess from their colon as a result of its contents having been rendered too fluid. With a return to a healthy degree of constipation their symptoms generally vanished.

I have no doubt that the tendency to migraine may be greatly increased by the artificial diarrhœa produced in an attempt to overcome a hypothetical poisoning from intestinal stasis, which either does not exist at all or which can be completely relieved by very little more than proper attention to the normal hygiene of the bowels. But even this intestinal toxæmia is not the cause of migraine; it is simply an accessory factor, which aggravates the liability to attacks by its deleterious effect on the general health. Thus a lady, 47 years of age, consulted me four and a half years ago for severe attacks of unilateral headache, occurring at least once a fortnight. They lasted for about 12 hours and were always accompanied by hemianopia and followed by nausea and vomiting. She had had much treatment for supposed "colitis," which was regarded as the cause of the migraine, though the latter began when she was 11 and the intestinal symptoms were of comparatively recent onset. Correction of her errors of refraction resulted in the immediate complete disappearance of her migraine, which has not recurred, but four years later she again consulted me for the so-called "colitis," which was simply the result of injudicious purging. She has now been taught to allow her bowels to look after themselves, with the result that during the last five months she has been completely fit in every way.

II. Psychical Factors.

A psychical stimulus is an occasional but comparatively unimportant factor. Sir John Herschell, one of the numerous astronomers who have suffered from migraine, found that he could induce attacks by picturing in his mind the visual phenomena which usually accompanied them. I have known a patient get an attack on seeing a wallpaper with a zigzag pattern which reminded her of her migraine, and the remarkable periodicity in individuals, who get attacks every Sunday morning or the first day of every menstrual period, may be partly a result of expectation leading to the suggestion of an attack, as well as to the fatigue of the week or the effect of the disturbance in the internal secretions of the body which recur at monthly intervals in women. As in asthma and in epilepsy, expectation and suggestion can only cause an attack in an individual who has the essential irritable centre in his brain; without that no amount of suggestion could conceivably give rise to a true attack of asthma, epilepsy, or migraine. In the case of asthma and epilepsy nothing more than hysterical tachypnœa and hysterical convulsions respectively would result in the absence of the essential constitutional factor, but I know of no corresponding hysterical imitation of migraine.

III. Reflex Factors: The Ocular Origin of Migraine.

I come now to the consideration of peripheral stimuli as possible causes of an attack of migraine. In the case of asthma irritation of the nasal and bronchial mucous membrane and distension of the stomach and the rectum are common reflex causes of attacks. Peripheral irritation from various parts of the body is occasionally an exciting cause of epileptic attacks, especially in children. In migraine there is only one place from which a similar exciting stimulus arises, but it is of fundamental importance, as I believe that in its absence no attacks can occur, though the irritable centre in the brain is a permanent condition, which can even be inherited from an individual whose father or mother had migraine, but who never has an attack himself, because the exciting reflex cause never comes into operation.

In 1828 Piorry drew attention to the fact that cases of migraine occur most frequently in people who work in ill-lighted rooms, read and write much, and lead a sedentary life in which their attention is constantly fixed on objects badly lighted or of very small size. He concluded that the malady or, at least, the variety associated with visual phenomena was due to irritation of the optic nerves occasioned by eye-strain.

After a long period of neglect Piorry's views were revived from time to time, and in recent years particularly by Ernest Clarke in England and Gould in America. On the other hand, most modern writers on migraine ignore the ocular factor entirely or consider it of quite minor importance, and very few give it the prominence which I am now convinced it ought to assume.

Being interested both in neurology and in digestive disorders, I have had the opportunity of seeing a very considerable number of cases of migraine. For a short time in 1915, before I went abroad on military service, I had the good fortune of working in association with Lieut.-Colonel R. H. Elliot, and during the last five years he has investigated all my cases. I can honestly say that my views with regard to prognosis have entirely altered since I have had the advantage of his help. All my cases before the war had their eyes examined, and they all had the usual medicinal and general treatment. But though many improved, few were cured. Now the improvement is almost always considerable, and complete cure is common. I am indebted to him for the following brief details as to the nature of the ocular defects which he finds are commonly associated with migraine.

Hyperopic astigmatism, especially when associated with latent hyperopia, is the most common error of refraction. Astigmatism, which is generally compound, is very rarely entirely absent. Very small errors are quite sufficient to give rise to migraine, especially in highly-strung clever people with a very irritable migraine storm-centre. For this reason the most accurate possible correction of every error is required. A well-known neurologist has recently written that "errors of refraction should be adjusted only if they are important." But even the smallest errors are, I am certain, always important, and to correct only gross errors has prevented him, like many other physicians and ophthalmologists, from realising the enormous benefit which follows sufficiently accurate ophthalmological treatment. Muscle balance defect may by itself cause migraine, though much more frequently it is associated with errors in refraction. Hyperphoria, or insufficiency of the superior and inferior recti, is the most important, and esophoria, or insufficiency of the external recti, is sometimes a factor; but exophoria, or insufficiency of the internal recti, is of little or no importance. Muscle balance should be accurately tested in every case both for near and distant vision, as a quite different correction may be required for each. It is this cause of eye-strain which is most frequently missed in the ocular treatment of patients with migraine, though small errors of refraction, especially in the form of astigmatism, are also too often neglected.

Diagnosis.

A typical attack of migraine is unmistakable. A paroxysmal attack of unilateral headache, preceded by visual disturbances and followed by nausea and vomiting, could hardly be due to anything else. But

The tenth-century Arabian physician, Serapion, differed little from those who to-day look upon the intestine as the origin of most of the ills of humanity, as he too believed that migraine was due to the movement of pernicious vapours from the alimentary canal to the pericranium, whilst Graaf of Leyden in his treatise, "De Clysteribus," published in 1688, wrote that "clysters relieve headaches by ridding the intestines of excremental humours, the vapour of which can rise to the brain." About the same time that great Oxford physician, Thomas Willis, added the spleen to the liver, stomach, and intestines as a source of the peccant humour which causes migraine.

(*a*) *Anaphylaxis: Toxic Idiopathies.*

The theory that migraine is a kind of anaphylactic phenomenon similar to asthma and dependent on a toxic idiopathy—a hyper-sensitiveness to certain proteins—is certainly attractive and requires consideration. I do not know whether anybody claims to have obtained positive cutaneous reactions to proteins in as large a proportion of cases of migraine as Walker appears to obtain in asthma. I heard so much about his work when I was in America in 1919 that I brought back a set of his dried proteins in order to investigate the question myself. But although we have systematically tested the cutaneous reactions in every case of asthma both at Guy's Hospital and New Lodge Clinic with the dried American proteins, and more recently with one or other of the liquid preparations which have now been put on the market by several British firms, we have hardly ever gained any information of the slightest value. The largest wheals I have seen were in a man in whom it had already been discovered that the proteins of goose feathers and tea gave big reactions. But we found that the solvent of the proteins gave an equally great reaction, the patient's skin being apparently unusually sensitive to the slightest irritation. I believe most of the extravagant claims, which have been made by the very small number of observers in England who believe they have confirmed Walker's work, are due to a similar fallacy, for the physician who had examined this patient has written that he does not think it necessary to do controls with the solvent of his proteins as standards for comparison with his supposed positive reactions. Needless to say, no improvement in the patient's condition had followed giving up tea or the use of a kapok pillow. Other treatment at the Clinic resulted, however, in the complete disappearance of his asthma; a goose-feather pillow was then substituted without his knowledge for his own kapok pillow, and he had a perfect night with no trace of asthma.

True cutaneous reactions are very commonly obtained with pollens in hay fever, but I quite agree with Freeman, who was the first to use this method of investigation, that it does not give any reliable information in more than 5 per cent. of asthmatics, and in our experience positive results are never obtained in migraine.

In spite of the small value of cutaneous tests in asthma, I believe that a toxic idiopathy is none the less very often present in addition to the irritable bronchial centre, the inherited and constitutional abnormality which is the only essential factor. But I have not been able to obtain the slightest clinical evidence that a toxic idiopathy is ever an exciting cause of attacks of migraine.

(*b*) *Internal Secretions.*

It is not surprising that the endocrinologist—I apologise for the term, but it is not my invention—regards migraine as coming within his sphere of action. The author of the article on migraine in a large international system of medicine, published since the war, recommends treatment by the oral administration of pituitary gland, to which may be added suprarenal gland and in some cases extract of corpus luteum, testicles, and pancreas. Such multi-glandular therapy has as much scientific basis for it as the electuary with which, in 1668, Riverius, physician to the King of France, cured "a choice virgin, Margaret de Varanda," of her migraine; it consisted of conserve of wormwood and maidenhair, elecampane roots, salt of tamarisk, magistry of tartar, and his "specifick aperitive powder."

Though most of what has been written on the connexion between the internally secreting glands and migraine is entirely speculative, there is no doubt that many women regularly have attacks immediately before or during the first day of each period, as was pointed out 150 years ago by John Fordyce, himself a sufferer, and the first English author to write a monograph on hemicrania. In such cases the attacks may completely cease during pregnancy, and permanent recovery may occur at the menopause. This must clearly be due to some endocrine activity connected with menstruation, which renders the storm-centre in the brain particularly sensitive at these times. But its exact nature is quite unknown.

(*c*) *Uric Acid.*

This short review of possible biochemical factors would indeed be incomplete if I did not refer to the uric acid theory of Alexander Haig. It is quite clear from the writings of John Fordyce, Sir Henry Holland, and Parry of Bath, who described exophthalmic goitre ten years before Graves and 15 years before Basedow, that gout and migraine, like gout and asthma, were often associated together, and this was still true in the gouty days of Trousseau. But, unfortunately, the disappearance of gout in England does not appear to have led to any diminution in the frequency of either migraine or asthma.

There was never any scientific basis for Haig's theory. I well remember seeing an outline drawing of a man, with the left half of his body chalked blue, which had been given to a relative of mine who suffered from left-sided hemicrania. He had been told that the capillary circulation of the part marked blue had been found to be sluggish and that this was due to excess of uric acid, which was also the cause of his migraine. It is curious to find in many of the most recent articles on the subject that a theory which has so little evidence in its support is still to some extent accepted, as a purin-free diet is often recommended, though an extensive trial has convinced me that no benefit resulted from this somewhat irksome treatment.

(*d*) *Gastro-intestinal Toxæmia.*

The majority of private cases of migraine I have seen since the war have been sent to me in the hope that I could find some metabolic disorder or some evidence of chronic toxæmia, the relief of which might cure their migraine. I must add that in at least one-half of the cases it had not previously been recognised that the condition from which the patient was suffering was migraine. Every case has been thoroughly investigated, but in no single instance have we found anything supporting the theory that migraine depends wholly or in part upon any form of gastro-intestinal toxæmia or metabolic disorder. Between the attacks gastric secretion is normal, the stools show no signs of deficient digestion or absorption, the urine is normal, and tests for estimating the functional capacity of the liver and kidneys show no deficiency. The stomach empties itself in the normal time, there is no ileal stasis, and there is no pathological delay in the passage through the colon. I have never found any justification for the view propounded by a recent writer in the *British Medical Journal* that migraine is due to recurrent attacks of dilatation of the stomach, as in no single case have we found any abnormality of the kind, and the author brings forward no evidence in support of his theory.

In some cases previous examinations with the X rays had led to a diagnosis of visceroptosis and chronic intestinal stasis, and the patients were wearing uncomfortable abdominal supports and dosing themselves with aperients, and many had had courses of Plombières douching. But both diagnoses had been made without bearing in mind how great are the normal variations. A pelvic cæcum and a greater curvature and transverse colon below the belt are, like a movable kidney, no more signs of disease than a crooked nose. They are frequently found in the healthy and vigorous, and the kinks and secondary adhesions, to which they are sometimes said to give rise, are almost always figments of the imagination. Many of the severest cases of intestinal toxæmia I have seen were in people who were poisoning themselves with aperients and with the toxins produced and absorbed in excess from their colon as a result of its contents having been rendered too fluid. With a return to a healthy degree of constipation their symptoms generally vanished.

I have no doubt that the *tendency to migraine* may be greatly increased by the artificial diarrhœa produced in an attempt to overcome a hypothetical poisoning from intestinal stasis, which either does not exist at all or which can be completely relieved by very little more than proper attention to the normal hygiene of the bowels. But even this intestinal toxæmia is not the cause of migraine; it is simply an accessory factor, which aggravates the liability to attacks by its deleterious effect on the general health. Thus a lady, 47 years of age, consulted me four and a half years ago for severe attacks of unilateral headache, occurring at least once a fortnight. They lasted for about 12 hours and were always accompanied by hemianopia and followed by nausea and vomiting. She had had much treatment for supposed "colitis," which was regarded as the cause of the migraine, though the latter began when she was 11 and the intestinal symptoms were of comparatively recent onset. Correction of her errors of refraction resulted in the immediate complete disappearance of her migraine, which has not recurred, but four years later she again consulted me for the so-called "colitis," which was simply the result of injudicious purging. She has now been taught to allow her bowels to look after themselves, with the result that during the last five months she has been completely fit in every way.

II. PSYCHICAL FACTORS.

A psychical stimulus is an occasional but comparatively unimportant factor. Sir John Herschell, one of the numerous astronomers who have suffered from migraine, found that he could induce attacks by picturing in his mind the visual phenomena which usually accompanied them. I have known a patient get an attack on seeing a wallpaper with a zigzag pattern which reminded her of her migraine, and the remarkable periodicity in individuals, who get attacks every Sunday morning or the first day of every menstrual period, may be partly a result of expectation leading to the suggestion of an attack, as well as to the fatigue of the week or the effect of the disturbance in the internal secretions of the body which recur at monthly intervals in women. As in asthma and in epilepsy, expectation and suggestion can only cause an attack in an individual who has the essential irritable centre in his brain; without that no amount of suggestion could conceivably give rise to a true attack of asthma, epilepsy, or migraine. In the case of asthma and epilepsy nothing more than hysterical tachypnœa and hysterical convulsions respectively would result in the absence of the essential constitutional factor, but I know of no corresponding hysterical imitation of migraine.

III. REFLEX FACTORS: THE OCULAR ORIGIN OF MIGRAINE.

I come now to the consideration of peripheral stimuli as possible causes of an attack of migraine. In the case of asthma irritation of the nasal and bronchial mucous membrane and distension of the stomach and the rectum are common reflex causes of attacks. Peripheral irritation from various parts of the body is occasionally an exciting cause of epileptic attacks, especially in children. In migraine there is only one place from which a similar exciting stimulus arises, but it is of fundamental importance, as I believe that in its absence no attacks can occur, though the irritable centre in the brain is a permanent condition, which can even be inherited from an individual whose father or mother had migraine, but who never has an attack himself, because the exciting reflex cause never comes into operation.

In 1828 Piorry drew attention to the fact that cases of migraine occur most frequently in people who work in ill-lighted rooms, read and write much, and lead a sedentary life in which their attention is constantly fixed on objects badly lighted or of very small size. He concluded that the malady or, at least, the variety associated with visual phenomena was due to irritation of the optic nerves occasioned by eye-strain.

After a long period of neglect Piorry's views were revived from time to time, and in recent years particularly by Ernest Clarke in England and Gould in America. On the other hand, most modern writers on migraine ignore the ocular factor entirely or consider it of quite minor importance, and very few give it the prominence which I am now convinced it ought to assume.

Being interested both in neurology and in digestive disorders, I have had the opportunity of seeing a very considerable number of cases of migraine. For a short time in 1915, before I went abroad on military service, I had the good fortune of working in association with Lieut.-Colonel R. H. Elliot, and during the last five years he has investigated all my cases. I can honestly say that my views with regard to prognosis have entirely altered since I have had the advantage of his help. All my cases before the war had their eyes examined, and they all had the usual medicinal and general treatment. But though many improved, few were cured. Now the improvement is almost always considerable, and complete cure is common. I am indebted to him for the following brief details as to the nature of the ocular defects which he finds are commonly associated with migraine.

Hyperopic astigmatism, especially when associated with latent hyperopia, is the most common error of refraction. Astigmatism, which is generally compound, is very rarely entirely absent. Very small errors are quite sufficient to give rise to migraine, especially in highly-strung clever people with a very irritable migraine storm-centre. For this reason the most accurate possible correction of every error is required. A well-known neurologist has recently written that "errors of refraction should be adjusted only if they are important." But even the smallest errors are, I am certain, always important, and to correct only gross errors has prevented him, like many other physicians and ophthalmologists, from realising the enormous benefit which follows sufficiently accurate ophthalmological treatment. Muscle balance defect may by itself cause migraine, though much more frequently it is associated with errors in refraction. Hyperphoria, or insufficiency of the superior and inferior recti, is the most important, and esophoria, or insufficiency of the external recti, is sometimes a factor; but exophoria, or insufficiency of the internal recti, is of little or no importance. Muscle balance should be accurately tested in every case both for near and distant vision, as a quite different correction may be required for each. It is this cause of eye-strain which is most frequently missed in the ocular treatment of patients with migraine, though small errors of refraction, especially in the form of astigmatism, are also too often reglected.

Diagnosis.

A typical attack of migraine is unmistakable. A paroxysmal attack of unilateral headache, preceded by visual disturbances and followed by nausea and vomiting, could hardly be due to anything else. But it must be remembered that the attacks vary greatly in different individuals, and even in the same individual. The visual phenomena are not often present in the remarkable forms, which have become classical as a result of the illustrated descriptions published by various distinguished sufferers. They may, indeed, be so slight that the patient does not mention them in describing his headaches and other symptoms, unless specially asked whether his sight is affected in his attacks. The headache, too, though generally the most prominent symptom, may be quite slight when the visual phenomena are most severe. Strictly speaking, a headache which is not unilateral ought not to be called by the English word megrim or the French migraine, which are simply mediæval corruptions of the Greek ἡμικρανία, or half-headache, but it is not uncommon for the other symptoms to be present in a quite characteristic form with a bilateral headache. It is true, however, that even when the whole head is affected, the pain is generally more severe on one side than the other, at any rate in some attacks. In rare cases neither nausea nor vomiting occurs; more commonly nausea and vomiting are such prominent symptoms that the patient makes light of everything else.

A great variety of other symptoms may occur with some or other of the three chief symptoms, or anomalous attacks may replace some of the typical migraine attacks. Thus disturbances in sensation and spasms or paresis may affect an arm or leg or one side of the face and tongue, and aphasia may accompany other symptoms involving the right side. In one case recurrent hemiplegia, with exaggerated deep reflexes and an extensor plantar reflex, was the prominent symptom, and a cerebral tumour had been diagnosed when I first saw the patient. But he had long been subject to migraine, and the hemiplegia was always associated with ocular symptoms and with a headache affecting the opposite side. The attacks ceased completely with treatment of the associated eye-strain. In some cases the patient may become confused or even have a definite attack of amnesia.

I have seen many cases in which the gastric symptoms were so pronounced that a diagnosis of some organic abdominal disorder had been made. As a matter of fact, such symptoms are quite unlike those caused by any primary gastric disorder, though the attacks of nausea without pain, which may occur in cholecystitis, are sometimes almost indistinguishable from the gastric symptoms of migraine, and they may also be accompanied by headache. In most cases a diagnosis can only be made by a careful inquiry into the associated symptoms and after a thorough investigation has failed to reveal any evidence of infection of the gall-bladder.

So-called bilious attacks in children are most frequently due either to migraine or to appendicitis. In this case again a detailed description of the attacks and a careful abdominal examination when an attack is actually present can alone point the way to a correct diagnosis. There does not appear to be any very sharp distinction between these "bilious attacks" and so-called "cyclical vomiting" of children. Out of 52 cases of cyclical vomiting observed in the Children's Department at Guy's Hospital, in which Dr. Osman was able to obtain a reliable family history, in no less than 23 the mother, or less frequently the father or some other relation, suffered from migraine, and 12 of these 23 had themselves been subject to cyclical vomiting as children. Cyclical vomiting appears therefore to be often, if not always, the expression in children of that type of cerebral storm-centre which gives rise to migraine in adults. The exciting factors in children are still unknown, but Osman has clearly shown that eye-strain, which is of fundamental importance in adults, has nothing to do with cyclical vomiting in children.

It is not generally recognised in England, though Mathieu and other French authors have frequently drawn attention to the subject, that diarrhœa may replace vomiting in some cases of migraine. It seems to be an exact equivalent, as the headache and nausea disappear as quickly after the bowels have been well opened as they generally do after vomiting, and in such cases an enema may abort an attack in the same way that washing out the stomach often does in the more usual form of migraine.

I am quite sure that numerous cases of migraine are missed owing to the ordinary text-book on medicine describing the classical attacks of migraine with the fortification spectrum and hemianopia, the unilateral headache, and the nausea and vomiting, without pointing out how unusual such attacks are, and without mentioning the far more common varieties together with the frequent *formes frustes*. Many of my patients had had an abdominal operation performed for the removal of an appendix, or, what was a far more serious mistake, part of the colon had been fixed, short-circuited, or removed for some hypothetical ptosis, kink, or adhesion, as such treatment not only did no good but actually produced abdominal symptoms which had not been present before.

I would suggest that in every case in which attacks of nausea occur, with or without vomiting or diarrhœa, but without definite abdominal pain, the possibility of migraine should be considered, and the patient should be questioned as to any associated headache, visual or other nervous symptoms. The possibility of migraine should also be considered in every case of paroxysmal headache, even if it is not strictly unilateral.

It is, of course, important to avoid making the opposite mistake. Just as typical epileptic attacks may be the first symptom of a cerebral tumour, so may symptoms very suggestive of migraine be due to the same cause, the tumour in this case being in the occipital lobe. Less commonly migraine attacks may be the first indication of the onset of uræmia, but an ordinary clinical examination should prevent the possibility of mistake in such a case.

PROGNOSIS.

Like the other paroxysmal neuroses, the only cure of migraine is not to have it, though, unfortunately, even this "cure" is not absolute. The storm-centre gets out of practice as time goes on, though it does not entirely forget how to act its old part. If an epileptic has no fit for three years, he can safely reduce his bromide, but I doubt whether it is wise for him to give it up entirely, even after an additional two or three years of freedom. I knew a man who had asthma from the age of 8 to 14. His family then removed from Southampton to South Africa. At the age of 39, after serving in the South African war, he came to England on a visit and landed at Southampton. He had had no asthma for 25 years, but had a severe attack on the night of his arrival. He fled to London, where he at once recovered, and he had had no further return when he left again for South Africa some months later—this time from another port, the atmosphere of which had not for him the asthmagenic properties of Southampton. With migraine the case is similar, and the spectacles which have caused the attacks to cease should be constantly worn. As the deficiency in muscle-balance may vary from time to time occasional re-examinations are useful, so that corresponding alterations in the prisms can be made when necessary. After some years of freedom from attacks, if the general health is good and vision for ordinary purposes satisfactory, the spectacles can perhaps be worn less constantly. But if the individual gets over-fatigued or goes through a period of physical or mental stress, a relapse is likely to occur unless the slightest tendency to eye-strain is continuously prevented. Thus I have known an attack of migraine occur after an interval of four years in a woman, whose very frequent and severe attacks had been completely arrested by proper glasses after prolonged drug treatment had failed. She had given up using them for over a year, when a period of unusual physical fatigue, accompanied by much worry, brought on the relapse. She at once returned to the discarded spectacles, and no further attacks occurred.

In most cases attacks of migraine become less severe and less frequent with advancing years, and spontaneous cure is not uncommon after the age of 50.

TREATMENT.

The most important part of treatment is the prevention of eye-strain. My object in choosing migraine as the subject of my lecture to-day will be attained if I can persuade practitioners, physicians, and oculists, whose past experience has led them to doubt the truth of this statement, to put it to the test once more. The author of the best recent clinical account of migraine I have read, in one of the most popular text-books of medicine of the day, writes that "very undue prominence has been given to the importance of errors of refraction as causes of migraine," and that "the majority of the subjects of migraine have no such errors of refraction, nor has the correction of such errors ever cured migraine." Personally I have never yet seen a case in which eye-strain was not present, and I have only seen two in which its correction did not either cure the patient or lead to very considerable improvement, and most of my patients had had prolonged treatment of various kinds before I saw them; some, indeed, had taken for months or even years the bromide, gelsemium, strychnine, and nitro-glycerine mixture first recommended by Gowers, which the distinguished neurologist, whose article I have just quoted, regards as his sheet-anchor in the treatment of migraine. The reason why the importance of the ocular factor is not more widely accepted is that few oculists trouble to give the attention to a patient with migraine that he requires. It is no doubt easy to correct an ordinary case of myopia, hypermetropia, or even astigmatism at a single interview of 15 or 30 minutes. But it is quite impossible to do this for a patient with migraine, as the smallest errors of refraction and every disturbance in muscle-balance require correction with absolute accuracy. This cannot be done in a hurry. At least three examinations on different days are required, the second being with the aid of a cycloplegic, and the third, 72 hours later, when the effect of the drug has completely disappeared. Muscle-balance defects are particularly difficult to correct, as their effect on the individual varies in degree from day to day, and even in the course of a single day. They are felt more in the evening when the patient is tired than when he is fresh in the morning, and at the end of a tiring week than after a restful Sunday. Their effect may temporarily disappear as the result of a country holiday, especially if the eyes are not used at all for any kind of near work. On the other hand, the resulting symptoms are exaggerated by anything, such as an attack of influenza, which impairs the general health.

Another difficulty is that many sufferers from migraine, far from having weak sight, as Piorry believed, are particularly proud of the excellence of their vision. They are very unwilling to consult an oculist at all, and still less willing to wear the spectacles he prescribes. In women often, and sometimes even in men, vanity stands in the way of cure, as a patient not infrequently hesitates whether the constant wearing of a disfiguring pair of spectacles is not too great a price to pay even for the relief of migraine.

The effect of preventing ocular strain is generally felt at once. In many cases attacks, which had occurred at frequent intervals for many years, cease immediately—never to return. In other cases they disappear less dramatically, but none the less surely; the intervals between them become more prolonged and they become less severe in character. Occasionally they actually become more intense and frequent for a short period, as with severe errors of refraction and disturbances in binocular muscle-balance it may take some time for the patient to become accustomed to the new conditions and for the strained extrinsic and intrinsic muscles of his eyes to relax. It is then often necessary to begin with a partial correction, and only gradually increase it until it is complete. Lastly, it must be remembered that the first attempt to overcome the eye-strain may be unsuccessful, generally owing to the patient's difficulty in answering questions correctly. In such cases he should be re-examined after having used his glasses continuously for three months, when it is usually possible to make quite accurate corrections. But if the symptoms persist and the first oculist consulted can do no more, then the help of another, and, if necessary, of yet another and another should be sought for until the desired object is attained. The first case which drew my attention to the fundamental importance of eye-strain was that of a young woman, who had had every kind of treatment and whose eyes had been examined and prescribed for on many occasions by four distinguished oculists without benefit, when she finally consulted a fifth, who was fortunate enough to discover and correct some deficiency in muscle-balance which had been missed by his predecessors. The cure was complete, as in the seven years which have since elapsed there has only been a single attack, and this resulted from giving up the spectacles at a time when the patient's general health was impaired.

Whilst the ocular factor is being dealt with it is often necessary to give some drug treatment, which will help meanwhile to reduce the frequency of attacks. Though arsenic has been used in countless cases since it was first recommended for the purpose by Bright, I have never convinced myself that it is of the slightest use. Bromide in small doses, as originally recommended by Liveing, and later by Charcot and by Gowers, appears to help some patients, but it has no effect in migraine in the least comparable to that which it has in epilepsy. The addition of gelsemium, nitro-glycerine, and strychnine in the mixture recommended by Gowers has not seemed to me to be any more effective than bromide given by itself. The only other really useful drug is luminal, which was, I think, first recommended for migraine by Wilfred Harris. A dose must be chosen which is just insufficient to produce any unpleasant degree of sleepiness, and this must be taken regularly. It can be given at the same time as the bromide, and the dose of both drugs can be increased for a few days when past experience indicates that an attack is imminent, as, for example, just before menstruation. The inconvenience caused by a slight amount of mental dullness and general sleepiness for a day or two is infinitely less than that caused by an attack in cases of any severity. But if the ocular defects have been adequately dealt with, it is not likely that drugs of any kind will have to be taken for longer than a few weeks, and in many cases it is unnecessary to take any at all. In a small minority of cases, however, complete relief only occurs if the prevention of eye-strain is associated with continuous medicinal treatment.

When other causes of ill-health, such as anæmia, dental or pharyngeal sepsis, gastric or intestinal dyspepsia, are found, they, of course, require suitable treatment. But though this may improve the general health, and thus make the patient get over the effects of an attack more quickly or even sometimes reduce their number, it is of quite secondary importance, and, as I have already pointed out, in a considerable majority of cases there is nothing of the kind which calls for treatment.

On the other hand, my experience shows quite definitely that attempts to treat supposed intestinal toxæmia by aperients, other digestive or metabolic disorders by freak diets, and endocrine deficiencies by glandular preparations—though happily most of the latter are completely inert—aggravate the patient's general health without influencing his migraine, and tend at the same time to add to the troubles of the unhappy subject of this paroxysmal neurosis by making him a hypochondriacal sufferer from a variety of imaginary complaints.

TREATMENT OF THE ATTACK.

I have little to say about the attack; it should be our object to prevent it rather than to treat it. But it must be remembered that the attacks vary greatly in different individuals, and even in the same individual. The visual phenomena are not often present in the remarkable forms, which have become classical as a result of the illustrated descriptions published by various distinguished sufferers. They may, indeed, be so slight that the patient does not mention them in describing his headaches and other symptoms, unless specially asked whether his sight is affected in his attacks. The headache, too, though generally the most prominent symptom, may be quite slight when the visual phenomena are most severe. Strictly speaking, a headache which is not unilateral ought not to be called by the English word megrim or the French migraine, which are simply mediæval corruptions of the Greek ἡμικρανία, or half-headache, but it is not uncommon for the other symptoms to be present in a quite characteristic form with a bilateral headache. It is true, however, that even when the whole head is affected, the pain is generally more severe on one side than the other, at any rate in some attacks. In rare cases neither nausea nor vomiting occurs; more commonly nausea and vomiting are such prominent symptoms that the patient makes light of everything else.

A great variety of other symptoms may occur with some or other of the three chief symptoms, or anomalous attacks may replace some of the typical migraine attacks. Thus disturbances in sensation and spasms or paresis may affect an arm or leg or one side of the face and tongue, and aphasia may accompany other symptoms involving the right side. In one case recurrent hemiplegia, with exaggerated deep reflexes and an extensor plantar reflex, was the prominent symptom, and a cerebral tumour had been diagnosed when I first saw the patient. But he had long been subject to migraine, and the hemiplegia was always associated with ocular symptoms and with a headache affecting the opposite side. The attacks ceased completely with treatment of the associated eye-strain. In some cases the patient may become confused or even have a definite attack of amnesia.

I have seen many cases in which the gastric symptoms were so pronounced that a diagnosis of some organic abdominal disorder had been made. As a matter of fact, such symptoms are quite unlike those caused by any primary gastric disorder, though the attacks of nausea without pain, which may occur in cholecystitis, are sometimes almost indistinguishable from the gastric symptoms of migraine, and they may also be accompanied by headache. In most cases a diagnosis can only be made by a careful inquiry into the associated symptoms and after a thorough investigation has failed to reveal any evidence of infection of the gall-bladder.

So-called bilious attacks in children are most frequently due either to migraine or to appendicitis. In this case again a detailed description of the attacks and a careful abdominal examination when an attack is actually present can alone point the way to a correct diagnosis. There does not appear to be any very sharp distinction between these "bilious attacks" and so-called "cyclical vomiting" of children. Out of 52 cases of cyclical vomiting observed in the Children's Department at Guy's Hospital, in which Dr. Osman was able to obtain a reliable family history, in no less than 23 the mother, or less frequently the father or some other relation, suffered from migraine, and 12 of these 23 had themselves been subject to cyclical vomiting as children. Cyclical vomiting appears therefore to be often, if not always, the expression in children of that type of cerebral storm-centre which gives rise to migraine in adults. The exciting factors in children are still unknown, but Osman has clearly shown that eye-strain, which is of fundamental importance in adults, has nothing to do with cyclical vomiting in children.

It is not generally recognised in England, though Mathieu and other French authors have frequently drawn attention to the subject, that diarrhœa may replace vomiting in some cases of migraine. It seems to be an exact equivalent, as the headache and nausea disappear as quickly after the bowels have been well opened as they generally do after vomiting, and in such cases an enema may abort an attack in the same way that washing out the stomach often does in the more usual form of migraine.

I am quite sure that numerous cases of migraine are missed owing to the ordinary text-book on medicine describing the classical attacks of migraine with the fortification spectrum and hemianopia, the unilateral headache, and the nausea and vomiting, without pointing out how unusual such attacks are, and without mentioning the far more common varieties together with the frequent *formes frustes*. Many of my patients had had an abdominal operation performed for the removal of an appendix, or, what was a far more serious mistake, part of the colon had been fixed, short-circuited, or removed for some hypothetical ptosis, kink, or adhesion, as such treatment not only did no good but actually produced abdominal symptoms which had not been present before.

I would suggest that in every case in which attacks of nausea occur, with or without vomiting or diarrhœa, but without definite abdominal pain, the possibility of migraine should be considered, and the patient should be questioned as to any associated headache, visual or other nervous symptoms. The possibility of migraine should also be considered in every case of paroxysmal headache, even if it is not strictly unilateral.

It is, of course, important to avoid making the opposite mistake. Just as typical epileptic attacks may be the first symptom of a cerebral tumour, so may symptoms very suggestive of migraine be due to the same cause, the tumour in this case being in the occipital lobe. Less commonly migraine attacks may be the first indication of the onset of uræmia, but an ordinary clinical examination should prevent the possibility of mistake in such a case.

PROGNOSIS.

Like the other paroxysmal neuroses, the only cure of migraine is not to have it, though, unfortunately, even this "cure" is not absolute. The storm-centre gets out of practice as time goes on, though it does not entirely forget how to act its old part. If an epileptic has no fit for three years, he can safely reduce his bromide, but I doubt whether it is wise for him to give it up entirely, even after an additional two or three years of freedom. I knew a man who had asthma from the age of 8 to 14. His family then removed from Southampton to South Africa. At the age of 39, after serving in the South African war, he came to England on a visit and landed at Southampton. He had had no asthma for 25 years, but had a severe attack on the night of his arrival. He fled to London, where he at once recovered, and he had had no further return when he left again for South Africa some months later—this time from another port, the atmosphere of which had not for him the asthmagenic properties of Southampton. With migraine the case is similar, and the spectacles which have caused the attacks to cease should be constantly worn. As the deficiency in muscle-balance may vary from time to time occasional re-examinations are useful, so that corresponding alterations in the prisms can be made when necessary. After some years of freedom from attacks, if the general health is good and vision for ordinary purposes satisfactory, the spectacles can perhaps be worn less constantly. But if the individual gets over-fatigued or goes through a period of physical or mental stress, a relapse is likely to occur unless the slightest tendency to eye-strain is continuously prevented. Thus I have known an attack of migraine occur after an interval of four years in a woman, whose very frequent and severe attacks had been completely arrested by proper glasses after prolonged drug treatment had failed. She had given up using them for over a year, when a period of unusual physical fatigue, accompanied by much worry, brought on the relapse. She at once returned to the discarded spectacles, and no further attacks occurred.

for for this purpose, and, when this is deficient, aceto-acetic and hydroxybutyric acids, poisonous substances, may be produced with very definite ill-results.

It might be urged that by increasing the carbohydrate in the food, the digestion of sugar would be so increased as to flood the blood with glucose, producing a hyperglycæmia, as in diabetes, and a consequent glycosuria. In practice this does not occur. To produce such a hyperglycæmia, in any but a diabetic person, it is necessary to secure a very rapid absorption of sugar from the intestine, and actually, unless glucose itself be given by the mouth, it is almost impossible to do this. The digestion of starch is slow enough to secure a steady and prolonged absorption of glucose without great excess at any given moment.

From what has been said above it follows that, if to a normal diet you add further carbohydrate, you will tend to increase the patient's supply of energy, and you will thus tend to fatten him. At the same time, you are providing that form of energy which is most easily accessible, and the one which throws the least additional work on the internal organs of metabolism and excretion.

But here it must be noted that we may give a diet containing increased carbohydrate and at the same time reduce the content of protein, of fat, or of both. What effect will this produce? (*a*) According to the extent of the carbohydrate addition the energy value of the food will or will not be such as will tend to fatten the patient. (*b*) Work by the liver and kidneys will be appreciably diminished by reduction of the protein, and digestion in the alimentary canal will be more easily accomplished on the removal of fat. These facts, however, bring us in contact with certain less desirable consequences. Too great a diminution in the protein must bring us to a point where the nitrogen intake may be insufficient for maintenance. Even in the full-grown individual the constant wear and tear of the living tissues leads to a continuous and important loss of nitrogen, and the protein intake must never be reduced below what is necessary to replace this loss. The amount of protein requisite for this purpose is not very large, and as a practical reality it is hard to reduce the protein below this safety-level without making the diet so unpalatable that the patient will reject it. Again, it must be borne in mind that anything like total exclusion of fat from the diet will cause a very great fall in the caloric value; weight for weight, fat gives more than twice the supply of energy that carbohydrate or protein do, and to get a diet which is rich in energy without containing fat means necessarily that such a diet will be very bulky.

An even greater danger attendant upon a diet low in protein and fat lies in the fact that such a diet may prove to contain insufficient vitamins. It is well established that one of the most important of these accessory food substances is most commonly associated with the animal fats; reduction of fat means reduction of the total amount of fat-soluble vitamin. This aspect of our problem is seen to be still more important when it is realised that vitamin deficiency is more marked in the presence of carbohydrate excess than with a generally low diet. On the one hand, we know that absolute starvation rarely leads to signs of deficiency diseases; on the other hand, it has been frequently observed that it is the pigeon which eats large quantities of polished rice which develops avian polyneuritis more rapidly than his more abstemious companions do. Fortunately it is easy to prepare a diet high in carbohydrate and low in protein and fat which yet contains abundant vitamins; the addition of a little marmite and a sufficiency of raw fruit or salad will readily secure this.

One most important effect of such a diet has not yet been mentioned, its action upon the flora of the alimentary canal. The problem of intestinal bacteriology is so immense, its complexity is so prodigious, that few bacteriologists have made any serious attempt to classify the organisms normally found in this site. Certain specific organisms, such as the *Bacillus typhosus* and the dysentery bacilli, have been isolated and closely studied; but common bacteriological technique consists of planting specimens of fæces on media which will kill all but a few of these specific organisms, rather than of making any endeavour to identify all the varieties which may be present. In view of the difficulty of the investigation, it is hardly surprising that our ideas on infection of intestinal origin remain vague.

But it is possible, even without considering the organisms known to cause specific disease, to point to two great groups of organisms normally present whose characters are widely divergent: these are, firstly, the indol-producing group, which live upon the products of protein digestion, and the acidophilous group, which prefer a carbohydrate diet. The first of these groups is thought to play a part, if indeed its members be not the direct cause, in many generalised infections; the organisms are typical putrefactive organisms, and when they are present in abundance, ethereal sulphates and indican are present in the urine. What is more important in connexion with the present lecture is that this group becomes rapidly replaced by the acidophilous group of organisms as soon as the patient is put on a high carbohydrate diet. One caution must be made here; the acidophilous group form gas with many sugars, and this excess of carbon dioxide does in some cases cause a certain amount of intestinal distension. It is not noticeable in the majority of cases, and when it does prove a difficulty it can often be overcome by giving saccharose or certain other sugars instead of glucose.

DISEASES IN WHICH HIGH CARBOHYDRATE DIETS ARE USEFUL.

I hope that from these introductory remarks on the functions of carbohydrate certain practical applications may already be evident. It is high time that we made a practice of choosing diets in accordance with some such principles. At the same time it would be unwise to attempt to make any complete list of diseases in which high carbohydrate is advisable, and the following indications do not pretend to do more than record a few examples where such a diet has proved of advantage.

First, we may consider cases amongst infants. For many years the protein of the diet was considered the all-important feature, but more recently, especially following certain widely-published German books, there has been a tendency to ascribe malnutrition in artificially fed babies more to errors in the amounts of carbohydrate or fat than of protein. Recent work by British, French, and American authorities has somewhat shaken the supposed scientific foundation of the work of Czerny and Finkelstein, but there remains a fairly strong consensus of opinion which favours the addition of carbohydrate to the diet of one group of these wasting infants. This group includes those described by Czerny as having the "exudative diathesis," others disagree with his clinical classification, and in general it may be said that consultation of many authorities tends to lead to increased confusion. This much may be asserted, however, that if a wasting baby has hard constipated motions consisting largely of fat and calcium soaps, great benefit can usually be secured by reducing the fat in the patient's diet, and increasing the carbohydrate, by means of dextrimaltose or some similar preparation. The subject, which is admirably dealt with by Dr. Leonard Parsons in his Goulstonian Lectures,[1] is too vast for further discussion here.

In adults and older children the following classification includes many of the indications for high carbohydrate diets.

1. *Certain Specific Infections.*

(*a*) *Pneumococcal pneumonia* provides an excellent illustration of the utility of such diets in acute diseases. My attention was long since directed to the fact that, if at autopsy you examine the stomach of a man who we have recently obtained an interesting sidelight on the subject in the course of investigating the digestive functions of two of our cases. In each case arrangements had been made for the patient to be examined with the X rays on a certain morning, and she was given her opaque meal, although on waking she had found that a slight attack of migraine was beginning. The X rays revealed a complete absence of peristalsis in the stomach, and at the end of six hours of voluntary starvation none of the opaque meal had passed through the pylorus into the duodenum. It was clear that digestion was in complete abeyance. It is obvious that any drug taken by mouth under such conditions would not reach the small intestine, from which alone it could be absorbed. This explains the futility of giving drugs when an attack has once begun. It explains also why the patient is generally unwilling to take food of any kind until the attack is over, and why, if he has already had a meal, his one desire is to eject it from his stomach as soon as possible. It is less easy to understand why relief should follow vomiting when no food has been eaten during the day, as nothing is brought up but a little mucous fluid, followed, if the vomiting is severe, by the scanty, bile-stained contents of the duodenum. But relief undoubtedly occurs, and in my experience the only means by which an attack can often, though not always, be aborted, is to induce vomiting by swallowing large quantities of warm water containing sodium bicarbonate or, when this fails, by actually washing out the stomach. Perhaps forcing the stomach to contract sends impulses up the vagus, which modify the "storm-centre" in such a way that it ceases to discharge.

---

[1] See THE LANCET, April 5th, 19th, and May 10th, 1924.

The wise practitioner and physician learn to draw sound conclusions from their own ophthalmoscopic observations in nervous and other diseases. But the examination of the eyes and their treatment in cases of migraine can only be undertaken by the specialist, and a specialist who is ready to devote much time to the study of the subject. The great advance in our knowledge of disorders of digestion during the last 20 years is largely due to a wise coöperation between the physician and the surgeon, the biochemist and the radiologist. Advance in our knowledge of the pathogenesis and treatment of migraine should come, I feel sure, through a similar close coöperation between the physician, the neurologist, and the ophthalmologist. The friends of the late Dr. Savill founded this lectureship in his memory as part of a scheme to *promote and encourage research and education* in neurology. I fear I have fulfilled my task inadequately, but if what I have said has the effect of stimulating the general practitioner, the physician, and the neurologist on the one hand, and the ophthalmic specialist on the other, and especially those whose experience in the direction I have indicated has not hitherto been encouraging, to investigate the subject without *arrière pensée*, I shall feel satisfied. For in its recurrent crippling influence on the work of men and women of the highest intelligence, during their years of greatest mental activity, migraine stands alone.

An Address

ON THE

THERAPEUTIC USES OF HIGH CARBOHYDRATE DIETS.

Delivered before the Leicester Medical Society

By T. IZOD BENNETT, M.D., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN AND ASSISTANT TO THE PROFESSOR OF PHYSIOLOGY, MIDDLESEX HOSPITAL; PHYSICIAN TO THE ROYAL NATIONAL ORTHOPÆDIC AND ST. SAVIOUR'S HOSPITALS; LATE BEIT MEMORIAL FELLOW FOR MEDICAL RESEARCH.

The subject of high carbohydrate diets is one well worthy of study for several reasons. In the first place, it is probably true to say that all existing treatises on dietetics contain masses of accumulated wisdom which are often devoid of any real scientific explanation. All of us can give examples of diets which are suitable or unsuitable in given conditions, but how seldom are we able to give a clear and logical explanation of such suitability or otherwise. From another point of view I feel this subject to be of interest, for we are becoming more and more aware of the weakness of the orthodox methods at our disposal for combating disease. Advances in our knowledge of pathology and of methods of diagnosis are so rapid that the house surgeon of to-day feels almost out of date when he compares what is taught to the junior clinical clerk with what he himself studied three or four years previously. It cannot be said that there is any similar rapid advance in the realm of therapeutics. If, then, we can envisage some new and broad therapeutic principle, we have made a considerable advance in our practical knowledge. I believe that high carbohydrate diets offer us a possibility in this respect.

PHYSIOLOGICAL SIGNIFICANCE OF CARBOHYDRATES IN DIET.

Let us begin by reviewing very briefly the physiological significance of the carbohydrate portion of our diet. The matter may be summarised in the shortest manner by saying that carbohydrates in the food are all reduced in the intestine to sugar, that they are absorbed in that form and subsequently serve as a source of energy, or, in other words, form the necessary fuel for the tissues.

But certain other considerations must be borne in mind which, if not fundamental, are of great practical importance to the physician.

(*a*) Carbohydrates are usually completely absorbed; even in diseases where diarrhœa is present it is unusual for any carbohydrate to escape complete digestion. And when some slight loss does occur it is rather on account of the cellulose envelope which shuts in the carbohydrate in certain vegetables, than on account of indigestibility of the carbohydrates themselves; when the carbohydrate food has been cooked, this cellulose envelope is almost invariably ruptured and the free starch then undergoes complete digestion. Very different is the state of affairs as regards the fats and the proteins; in diarrhœal diseases, in jaundice, or with faulty pancreatic secretion, the loss of one or both of these constituents may be very considerable.

(*b*) After absorption the carbohydrates require no great work on the part of the tissues in the process of their combustion and the elimination of their end-products. The absorbed sugar passes up the portal vein to the liver and thence to the general circulation, being burnt up according to the activity of the muscles and other tissues, or being stored first as glycogen and then perhaps as fat, if it be in excess of the energy needs of the moment. The end-products of combustion are singularly easy for the body to dispose of. The carbonic acid gas is readily eliminated by the lungs without effort or inconvenience of any kind; water, the only other end-product, is eliminated with equal ease by the kidney, and, be it noted, elimination of water by the skin can be readily performed if the renal function is below par. Proteins, on the other hand, after their absorption as amino-acids, must for the most part be substantially changed by the liver, the denitrification of these bodies calls for an appreciable amount of work by that organ, and the end-products so formed—urea, uric acid, and other nitrogenous substances—charge the blood with, at best, inert products, which require work from the kidneys before they can be eliminated. Nor are the fats less exacting. We know that they are after absorption less readily burnt up than the other foods. An actual provision of oxygen is called for for this purpose, and, when this is deficient, aceto-acetic and hydroxybutyric acids, poisonous substances, may be produced with very definite ill-results.

It might be urged that by increasing the carbohydrate in the food, the digestion of sugar would be so increased as to flood the blood with glucose, producing a hyperglycæmia, as in diabetes, and a consequent glycosuria. In practice this does not occur. To produce such a hyperglycæmia, in any but a diabetic person, it is necessary to secure a very rapid absorption of sugar from the intestine, and actually, unless glucose itself be given by the mouth, it is almost impossible to do this. The digestion of starch is slow enough to secure a steady and prolonged absorption of glucose without great excess at any given moment.

From what has been said above it follows that, if to a normal diet you add further carbohydrate, you will tend to increase the patient's supply of energy, and you will thus tend to fatten him. At the same time, you are providing that form of energy which is most easily accessible, and the one which throws the least additional work on the internal organs of metabolism and excretion.

But here it must be noted that we may give a diet containing increased carbohydrate and at the same time reduce the content of protein, of fat, or of both. What effect will this produce? (*a*) According to the extent of the carbohydrate addition the energy value of the food will or will not be such as will tend to fatten the patient. (*b*) Work by the liver and kidneys will be appreciably diminished by reduction of the protein, and digestion in the alimentary canal will be more easily accomplished on the removal of fat. These facts, however, bring us in contact with certain less desirable consequences. Too great a diminution in the protein must bring us to a point where the nitrogen intake may be insufficient for maintenance. Even in the full-grown individual the constant wear and tear of the living tissues leads to a continuous and important loss of nitrogen, and the protein intake must never be reduced below what is necessary to replace this loss. The amount of protein requisite for this purpose is not very large, and as a practical reality it is hard to reduce the protein below this safety-level without making the diet so unpalatable that the patient will reject it. Again, it must be borne in mind that anything like total exclusion of fat from the diet will cause a very great fall in the caloric value; weight for weight, fat gives more than twice the supply of energy that carbohydrate or protein do, and to get a diet which is rich in energy without containing fat means necessarily that such a diet will be very bulky.

An even greater danger attendant upon a diet low in protein and fat lies in the fact that such a diet may prove to contain insufficient vitamins. It is well established that one of the most important of these accessory food substances is most commonly associated with the animal fats; reduction of fat means reduction of the total amount of fat-soluble vitamin. This aspect of our problem is seen to be still more important when it is realised that vitamin deficiency is more marked in the presence of carbohydrate excess than with a generally low diet. On the one hand, we know that absolute starvation rarely leads to signs of deficiency diseases; on the other hand, it has been frequently observed that it is the pigeon which eats large quantities of polished rice which develops avian polyneuritis more rapidly than his more abstemious companions do. Fortunately it is easy to prepare a diet high in carbohydrate and low in protein and fat which yet contains abundant vitamins; the addition of a little marmite and a sufficiency of raw fruit or salad will readily secure this.

One most important effect of such a diet has not yet been mentioned, its action upon the flora of the alimentary canal. The problem of intestinal bacteriology is so immense, its complexity is so prodigious, that few bacteriologists have made any serious attempt to classify the organisms normally found in this site. Certain specific organisms, such as the *Bacillus typhosus* and the dysentery bacilli, have been isolated and closely studied; but common bacteriological technique consists of planting specimens of fæces on media which will kill all but a few of these specific organisms, rather than of making any endeavour to identify all the varieties which may be present. In view of the difficulty of the investigation, it is hardly surprising that our ideas on infection of intestinal origin remain vague.

But it is possible, even without considering the organisms known to cause specific disease, to point to two great groups of organisms normally present whose characters are widely divergent: these are, firstly, the indol-producing group, which live upon the products of protein digestion; and the acidophilous group, which prefer a carbohydrate diet. The first of these groups is thought to play a part, if indeed its members be not the direct cause, in many generalised infections; the organisms are typical putrefactive organisms, and when they are present in abundance, ethereal sulphates and indican are present in the urine. What is more important in connexion with the present lecture is that this group becomes rapidly replaced by the acidophilous group of organisms as soon as the patient is put on a high carbohydrate diet. One caution must be made here; the acidophilous group form gas with many sugars, and this excess of carbon dioxide does in some cases cause a certain amount of intestinal distension. It is not noticeable in the majority of cases, and when it does prove a difficulty it can often be overcome by giving saccharose or certain other sugars instead of glucose.

DISEASES IN WHICH HIGH CARBOHYDRATE DIETS ARE USEFUL.

I hope that from these introductory remarks on the functions of carbohydrate certain practical applications may already be evident. It is high time that we made a practice of choosing diets in accordance with some such principles. At the same time it would be unwise to attempt to make any complete list of diseases in which high carbohydrate is advisable, and the following indications do not pretend to do more than record a few examples where such a diet has proved of advantage.

First, we may consider cases amongst infants. For many years the protein of the diet was considered the all-important feature, but more recently, especially following certain widely-published German books, there has been a tendency to ascribe malnutrition in artificially fed babies more to errors in the amounts of carbohydrate or fat than of protein. Recent work by British, French, and American authorities has somewhat shaken the supposed scientific foundation of the work of Czerny and Finkelstein, but there remains a fairly strong consensus of opinion which favours the addition of carbohydrate to the diet of one group of these wasting infants. This group includes those described by Czerny as having the "exudative diathesis," others disagree with his clinical classification, and in general it may be said that consultation of many authorities tends to lead to increased confusion. This much may be asserted, however, that if a wasting baby has hard constipated motions consisting largely of fat and calcium soaps, great benefit can usually be secured by reducing the fat in the patient's diet, and increasing the carbohydrate, by means of dextrimaltose or some similar preparation. The subject, which is admirably dealt with by Dr. Leonard Parsons in his Goulstonian Lectures,[1] is too vast for further discussion here.

In adults and older children the following classification includes many of the indications for high carbohydrate diets.

1. *Certain Specific Infections.*

(*a*) *Pneumococcal pneumonia* provides an excellent illustration of the utility of such diets in acute diseases. My attention was long since directed to the fact that, if at autopsy you examine the stomach of a man who we have recently obtained an interesting sidelight on the subject in the course of investigating the digestive functions of two of our cases. In each case arrangements had been made for the patient to be examined with the X rays on a certain morning, and she was given her opaque meal, although on waking she had found that a slight attack of migraine was beginning. The X rays revealed a complete absence of peristalsis in the stomach, and at the end of six hours of voluntary starvation none of the opaque meal had passed through the pylorus into the duodenum. It was clear that digestion was in complete abeyance. It is obvious that any drug taken by mouth under such conditions would not reach the small intestine, from which alone it could be absorbed. This explains the futility of giving drugs when an attack has once begun. It explains also why the patient is generally unwilling to take food of any kind until the attack is over, and why, if he has already had a meal, his one desire is to eject it from his stomach as soon as possible. It is less easy to understand why relief should follow vomiting when no food has been eaten during the day, as nothing is brought up but a little mucous fluid, followed, if the vomiting is severe, by the scanty, bile-stained contents of the duodenum. But relief undoubtedly occurs, and in my experience the only means by which an attack can often, though not always, be aborted, is to induce vomiting by swallowing large quantities of warm water containing sodium bicarbonate or, when this fails, by actually washing out the stomach. Perhaps forcing the stomach to contract sends impulses up the vagus, which modify the "storm-centre" in such a way that it ceases to discharge.

---

[1] See THE LANCET, April 5th, 19th, and May 10th, 1924.

The wise practitioner and physician learn to draw sound conclusions from their own ophthalmoscopic observations in nervous and other diseases. But the examination of the eyes and their treatment in cases of migraine can only be undertaken by the specialist, and a specialist who is ready to devote much time to the study of the subject. The great advance in our knowledge of disorders of digestion during the last 20 years is largely due to a wise coöperation between the physician and the surgeon, the biochemist and the radiologist. Advance in our knowledge of the pathogenesis and treatment of migraine should come, I feel sure, through a similar close coöperation between the physician, the neurologist, and the ophthalmologist. The friends of the late Dr. Savill founded this lectureship in his memory as part of a scheme to promote and encourage research and education in neurology. I fear I have fulfilled my task inadequately, but if what I have said has the effect of stimulating the general practitioner, the physician, and the neurologist on the one hand, and the ophthalmic specialist on the other, and especially those whose experience in the direction I have indicated has not hitherto been encouraging, to investigate the subject without *arrière pensée*, I shall feel satisfied. For in its recurrent crippling influence on the work of men and women of the highest intelligence, during their years of greatest mental activity, migraine stands alone.

An Address

ON THE

THERAPEUTIC USES OF HIGH CARBOHYDRATE DIETS.

Delivered before the Leicester Medical Society

BY T. IZOD BENNETT, M.D., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN AND ASSISTANT TO THE PROFESSOR OF PHYSIOLOGY, MIDDLESEX HOSPITAL; PHYSICIAN TO THE ROYAL NATIONAL ORTHOPÆDIC AND ST. SAVIOUR'S HOSPITALS; LATE BEIT MEMORIAL FELLOW FOR MEDICAL RESEARCH.

THE subject of high carbohydrate diets is one well worthy of study for several reasons. In the first place, it is probably true to say that all existing treatises on dietetics contain masses of accumulated wisdom which are often devoid of any real scientific explanation. All of us can give examples of diets which are suitable or unsuitable in given conditions, but how seldom are we able to give a clear and logical explanation of such suitability or otherwise. From another point of view I feel this subject to be of interest, for we are becoming more and more aware of the weakness of the orthodox methods at our disposal for combating disease. Advances in our knowledge of pathology and of methods of diagnosis are so rapid that the house surgeon of to-day feels almost out of date when he compares what is taught to the junior clinical clerk with what he himself studied three or four years previously. It cannot be said that there is any similar rapid advance in the realm of therapeutics. If, then, we can envisage some new and broad therapeutic principle, we have made a considerable advance in our practical knowledge. I believe that high carbohydrate diets offer us a possibility in this respect.

PHYSIOLOGICAL SIGNIFICANCE OF CARBOHYDRATES IN DIET.

Let us begin by reviewing very briefly the physiological significance of the carbohydrate portion of our diet. The matter may be summarised in the shortest manner by saying that carbohydrates in the food are all reduced in the intestine to sugar, that they are absorbed in that form and subsequently serve as a source of energy, or, in other words, form the necessary fuel for the tissues.

But certain other considerations must be borne in mind which, if not fundamental, are of great practical importance to the physician.

(*a*) Carbohydrates are usually completely absorbed; even in diseases where diarrhœa is present it is unusual for any carbohydrate to escape complete digestion. And when some slight loss does occur it is rather on account of the cellulose envelope which shuts in the carbohydrate in certain vegetables, than on account of indigestibility of the carbohydrates themselves; when the carbohydrate food has been cooked, this cellulose envelope is almost invariably ruptured and the free starch then undergoes complete digestion. Very different is the state of affairs as regards the fats and the protëins; in diarrhœal diseases, in jaundice, or with faulty pancreatic secretion, the loss of one or both of these constituents may be very considerable.

(*b*) After absorption the carbohydrates require no great work on the part of the tissues in the process of their combustion and the elimination of their end-products. The absorbed sugar passes up the portal vein to the liver and thence to the general circulation, being burnt up according to the activity of the muscles and other tissues, or being stored first as glycogen and then perhaps as fat, if it be in excess of the energy needs of the moment. The end-products of combustion are singularly easy for the body to dispose of. The carbonic acid gas is readily eliminated by the lungs without effort or inconvenience of any kind; water, the only other end-product, is eliminated with equal ease by the kidney, and, be it noted, elimination of water by the skin can be readily performed if the renal function is below par. Proteins, on the other hand, after their absorption as amino-acids, must for the most part be substantially changed by the liver, the denitrification of these bodies calls for an appreciable amount of work by that organ, and the end-products so formed—urea, uric acid, and other nitrogenous substances—charge the blood with, at best, inert products, which require work from the kidneys before they can be eliminated. Nor are the fats less exacting. We know that they are after absorption less readily burnt up than the other foods. An actual provision of oxygen is called practice of giving a dessertspoonful in a tumbler of water occasionally is of little use. My practice is to have a strong solution, made by dissolving over half a pound of glucose in a quart of boiling water, in which two lemons are steeped; when cooled this makes a very palatable drink, and I have found it easy to administer sometimes nearly a pound of glucose a day in this manner. The administration must be spaced out as much as possible, or else a good deal of the sugar will escape in the urine, but even here there is no danger unless the patient be a diabetic. In cases of chronic hepatic disease the indication is to give starches with very low protein, as in the diseases discussed in the next paragraph.

6. *The Renal System* supplies further indications for high carbohydrate diets. We are to-day inclining more and more to consider nephritis from the point of view of the biochemist rather than from that of the morbid anatomist. When faced with a case of chronic nephritis we inquire whether this patient is affected more by an inability to excrete salts or by a failure to eliminate the nitrogenous waste-products. The French have long made the useful distinction between the hydropigenous or dropsical patient, and the azotæmic or uræmic one.

Modern biochemical tests, such as the urea-concentration test, or the estimation of urea and non-protein nitrogen on the blood, aim at determining the capacity of the kidney for eliminating the nitrogenous waste products. When such tests inform us that the capacity of the kidney for performing this function is diminished, we are immediately faced with an indication for a diet in which the carbohydrate proportion is increased and the protein reduced. One cannot but be astonished at the frequency with which patients with acute nephritis are encouraged to imbibe large quantities of milk, a diet for which, to say the least of it, there is no scientific indication. I would say that in acute nephritis glucose is again the food for which there is a call, as it is the one which alone yields harmless end-products, and that in chronic cases, where there is diminished nitrogen excretion, starch rather than protein must be chosen.

There are many medical and surgical conditions to which I have made no allusion, but I hope that I have given some indication of the wide and useful field for the application of high carbohydrate diets; it remains to say a few words as to how such a diet may be chosen. I have already mentioned the strong glucose solution which I have found so useful in acute cases; it is also of value in more chronic ones if used sparingly and as an adjuvant to the diet. In these cases it should be given in such doses that the blood is never over-charged with sugar, and hence no glycosuria is produced; this is merely a question of spacing out the feeds properly.

Of foods, the most useful group is that which are known in France as pâtes: macaroni, vermicelli, nouilles, and various substances prepared from flour, arrowroot, sago, and other starchy substances. The list makes one reflect on the sad state into which the art of cooking has fallen in this country. In Italy or in any southern country the preparation of these foods is an everyday matter, yielding delicious results; here it is often impossible to obtain them in palatable form. Many of the starchy vegetables—potatoes, carrots, artichokes, &c.—are most useful, as are also the cereal foods, a great variety of which are now imported from the United States. A good book of diet tables is of much value to the practitioner in devising such a diet.

In chronic cases fresh fruit is often invaluable, not on account of its carbohydrate content, but because it enables us to supply that measure of palatability which is very essential for the well-being of our patients; it has the further advantage of giving sufficient cellulose to maintain the bulk of the fæces and so prevent constipation, and of ensuring a plentiful supply of vitamins.

SPLANCHNIC ANALGESIA.

By O. STANLEY HILLMAN, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

OPERATIONS on the upper abdomen are attended with a certain mortality, the causes of which may be numerous, but probably shock and chest complications are the greatest contributors to this mortality. It is obvious, therefore, that if some procedure can be used which will combat these two evils, a great improvement will have been made in abdominal surgery. The chest complications are due to prolonged inhalation anæsthesia, combined with which is the fact that the operative field lies immediately under the diaphragm, the movements of which must of necessity be impeded. The smaller movements of the diaphragm result in stagnation in the bases of the lungs, thus predisposing them to inflammatory complications induced by the irritant vapour. The shock is caused by repeated harmful stimuli passing to the central nervous system via the semilunar ganglia and splanchnic nerves, which supply the visceral peritoneum and intestinal tract.

Is there, then, some means of reducing the amount of anæsthetic administered, and at the same time cutting off the harmful impulses passing up the splanchnic nerves? The answer is found in splanchnic analgesia, with which this article deals.

Technique.

Splanchnic analgesia has been used for some time on the Continent and in America, and it was at Mr. G. Gordon-Taylor's suggestion that I investigated its possibilities, and through his kindness I have been able to use this method on patients from his wards at the Middlesex Hospital. The technique used is not original, but is that described in Gaston Labat's book on Regional Anæsthesia. The principle of splanchnic analgesia is that novocaine is deposited close to the semilunar ganglia and cœliac plexus so as to cut off the impulses passing from these nerves, thus enabling the viscera to be handled without causing pain or shock.

To give a brief description of the anatomy of the parts involved, the cœliac plexus consists of the cœliac or semilunar ganglia which lie on either side of the commencement of the abdominal aorta at the origin of the cœliac axis artery. The two ganglia lie on the crura of the diaphragm, that on the right lying behind the inferior vena cava. They lie internal to the suprarenal glands, and are at the level of the first lumbar vertebra. The two ganglia are connected together, in front of the aorta and around the origin of the cœliac axis artery, by a plexus of nerves which, with the ganglia, constitute the cœliac or solar plexus. Entering the upper part of the plexus are the great splanchnic nerves, which are derived from the thoracic sympathetic chain and primarily from the fifth to the ninth or tenth dorsal nerves, the nerves piercing the crura of the diaphragm to reach the plexus. From the plexus secondary plexuses pass to the abdominal viscera and visceral peritoneum.

It will be seen that the neighbourhood of the plexus to be injected is one which is not to be approached except with great care and delicacy, because of the proximity of the large vessels; therefore it is necessary for anyone taking up this procedure to familiarise himself with the anatomy of this region, and by repeated practice on the cadaver to make sure of the method and technique. The route adopted has been the posterior one, using a fine needle 12 cm. long. In those cases in which the operation is carried as far as possible without any general anæsthetic, preliminary injections of morphine and scopolamine are given, but if a light general anæsthetic is administered from the commencement then the usual injection of morphine and atropine is used instead.

The method of procedure is as follows: The patient is placed on the side opposite that to be injected, with a small pillow placed under the loin to prevent has died of pneumonia, you will usually find, stagnating within it, all the food given him for several days prior to his death. The disease is too violent in its onslaught for normal digestion to be possible, and, if we remember that the period before the crisis rarely lasts ten days, it becomes clear that a highly digestible dietary, containing readily assimilable energy, is all that can be needed during this time. Glucose is the ideal substance for such a purpose, and I have found that repeated feeds of the strong glucose solution, which I shall describe later, is of great service in these cases. Beyond this all food given before the crisis need be no more than a placebo, and it is indeed of benefit to keep its amount very small.

(*b*) *In typhoid and paratyphoid infections* the utility of carbohydrates has long been recognised. Whether the administration of these with very limited protein has an actual effect in reducing the infecting organisms in the intestine is, to my mind, doubtful; the beneficial effects of starches and sugars are probably more due to their ready assimilability and the plentiful energy which they supply. In this group of diseases gas formation to which I have alluded must be watched for, as it may sometimes prove very uncomfortable.

(*c*) *In Bacillus coli communis infections* a high carbohydrate diet, with very reduced protein, often appears to be of the utmost service in checking an attack and preventing relapses. Sir Thomas Horder has laid emphasis on this line of treatment, and my own experience is in close agreement with his. These cases, especially those in which the urinary tract is involved, are frequently so resistant to treatment that any possible therapeutic aid is of value; my personal belief is that, if proper attention be given to the diet, in addition to the more usual therapeutic procedures, the course of these troublesome cases is materially shortened. Needless to say, in view of their chronic nature, the diet must be amply sufficient; starches rather than sugars should be chosen, and the protein reduction rigidly enforced, not only by excluding meat, but also by reducing articles such as milk and bread, which contain very appreciable quantities of protein, and by substituting more purely carbohydrate foods.

2. *In Certain Infections of Unknown Origin*, especially some cases of rheumatoid arthritis, great help is afforded by these methods of dieting. About 18 months ago we had the pleasure of welcoming to London Dr. Guelpa, of Paris, who introduced, many years since, a method of treating diabetes, somewhat akin to the modern fasting treatments. Guelpa's treatment consists of fasting and purgation, and, apart from cases of diabetes, I have sometimes seen this treatment produce the most happy results in cases of rheumatoid arthritis which had resisted all other forms of treatment. It is, I believe, worth treating such cases, where the origin of the infection is obscure, and other treatment has failed, by starvation and brisk purgation for several days, followed by a diet consisting chiefly of carbohydrate on the lines I have already indicated.

3. *Diseases of the Heart and Blood-vessels* provide fairly frequent examples of cases in whom this treatment is of use. In cardiac failure we have to avoid throwing extra work on the alimentary canal and the liver; moreover, a plentiful supply of sugar to the blood is often a potent factor in aiding the damaged cardiac muscle. Again, in arterio-sclerotic individuals it is a manifest advantage to supply them with the food that yields sugar, rather than the proteins which call for more metabolic work and a tedious excretion of nitrogenous substances.

4. *Respiratory Diseases* are seldom indications for this diet. Pneumonia has been mentioned. A few obscure cases of asthma have been traced to ingested proteins to which the subject is sensitive, and here carbohydrate replacement may be of use.

5. *The Alimentary System* gives us so many examples that a few only can be quoted. In cases of peptic ulcer, fluid and semi-fluid carbohydrate diets are now used extensively. I think the scientific basis is sound, and I am convinced that the practical utility is great. The main principle, as employed in the Sippy treatment, is to give small frequent feeds the carbohydrate nature of which is least likely to excite gastric secretion and which will never be long delayed in the stomach.

A still more numerous group of diseases of the alimentary tract is that in which undernutrition is the most outstanding feature. It would be out of place to describe these here in detail; I would but say that I refer to that class of patient whom one encounters so frequently, in whom, whether there be an organic lesion present or not, abdominal pain and discomfort have led to curtailment of the diet, loss of weight has aggravated the symptoms, and starvation and undernutrition have become the most prominent physical features. In such patients it is often essential to secure a diet which will not only sustain life, but will also help them to restore their lost subcutaneous and intra-abdominal fat, and usually a high carbohydrate diet is the method of choice for securing this. Such patients are often peculiarly intolerant to fat, and I feel this question is one which will repay much closer study in the future; for the moment I would impress upon you that, when fat cannot be tolerated, a high carbohydrate diet becomes essential if loss of weight is to be prevented.

A further group which must be considered with alimentary diseases is that embracing disorders of the liver. Fat digestion is here frequently imperfect; it is a matter of common knowledge that in practically all jaundiced states the paucity of bile-salts in the alimentary canal leads to a failure of absorption of fat. But note, in addition, that protein metabolism is also seriously affected, for the amino-acids, when absorbed, must in large measure be denitrified by the liver, and, therefore, a high protein diet is one calling for considerable hepatic activity. We must therefore conclude that neither fat nor protein can usefully be administered in any large quantity in such diseases.

But it may be urged that the glycogenetic function of the liver will also be impaired, and that therefore a high carbohydrate diet is equally inapplicable. I do not think this reasoning is correct; the storage of glycogen is but a temporary expedient, useful for securing a steady regulation of the blood-sugar, but not a cardinal necessity, and it is highly probable that if its capacity for storing glycogen is impaired the liver will merely allow the glucose which reaches it by the portal vein to transude into the systemic blood, thus giving a plentiful but somewhat irregular supply of sugar to the tissues.

I can say with emphasis that in acute cases of hepatic disease high carbohydrate, especially when given in the form of glucose, is often of remarkable value. A recent case of this type which I saw was one of delayed chloroform poisoning following prolonged anæsthesia; the administration of large quantities of glucose in solution by mouth produced a most dramatic recovery.

Much interesting experimental work dealing with the total extirpation of the liver in dogs has recently been performed by Mann in the United States; he found that, after recovery from the operation, the animals passed suddenly, after some hours of good health, into a condition of coma with muscular twitchings clinically comparable to the hypoglycæmic convulsions produced by an overdose of insulin; from this condition they were rapidly, though temporarily, restored by the intravenous injection of glucose.

I am convinced that this gives us the clue to the right line of treatment for cases of acute hepatic disease such as eclampsia, acute yellow atrophy, poisoning by chloroform, salvarsan, phosphorus, or other drugs. In these cases a plentiful supply of glucose must be attained, and this is usually easy if we give a strong solution by mouth. The current was induced in the usual way, but instead of performing an abdominal field block a paravertebral dorsal block was performed, blocking the ninth to twelfth dorsal nerves on both sides. Without any general anæsthesia the abdomen was opened from just above the umbilicus to the pubis, and a large malignant ovarian cyst removed, without the patient showing signs of feeling pain, except when the pelvis was swabbed out, which was to be expected. The swabbing of the pelvis having aroused the patient, she was given some ether, which amounted to ʒ iii. only, and the abdomen closed. The patient subsequently said that she had not felt any part of the operation except the preliminary injections.

Another case of gastrectomy being performed on a patient who had already a gastro-enterostomy is the following:—

A woman, aged 46 years, had had a gastro-jejunostomy performed five years previously, and for the last two years had had repeated attacks of pain and vomiting; she was very weak and a poor subject in every way. The usual routine was followed, ether being given throughout the operation. As usual with this type of case the operation was extremely difficult, and the adhesions around the gastro-jejunal ulcer which were present increased the difficulties. The operation lasted two hours; the patient's pulse-rate was 100 at the commencement, but it fell to 82 during the operation, and at the end it was 88. During convalescence the patient was so well that she might have had only a very minor operation; her pulse-rate never rose above 88 and fell to 72 on the third day.

Before concluding, I would like to quote one other case of interest as being one in whom I failed to be able to reach the front of the body of the first lumbar vertebra and yet managed to block the splanchnic nerves by blocking the dorsal nerves a short distance from their exit from the spine by a paravertebral dorsal block.

This patient was a young man, aged 32 years, who gave a very definite history of a chronic gastric ulcer. He was very ill, wasted, and anæmic, and subject to attacks of agonising pain in the back, due to involvement of the pancreas in the ulcer, with the result that he had had little sleep for weeks, and was both a physical and mental wreck. It was decided to operate on him with splanchnic analgesia, but owing to his very nervous condition it was decided to give him some ether from the commencement.

An attempt was made to block the cœliac ganglion in the usual way, but owing to a very narrow angle between the last rib and the spine, or to a long transverse process to the first lumbar vertebra it was impossible, after once striking the body of the vertebra, to alter the angle of the needle without striking either the last rib or the first lumbar transverse process. After repeated trials on both sides I decided to give it up and block the seventh to eleventh dorsal nerves close to their exit from the foramina, with the hope that the novocaine would diffuse forwards, and also block the splanchnic nerves and grey rami communicantes. That this occurred there is no doubt.

Mr. Gordon-Taylor performed a total gastrectomy on this patient, as the ulcer was so large that it extended very close to the cardiac orifice of the stomach, its floor being formed by the pancreas. The operation lasted two hours, and although the manipulations were carried right up to the œsophageal orifice of the diaphragm and most dense adhesions dealt with, the respirations of the patient did not alter, and very little ether was administered to him. His pulse-rate was 100 at the commencement and 132 at the end of the operation, and subsequently he made a good recovery, though the day following the operation he was in a very weak state. Both Mr. Gordon-Taylor and Mr. H. P. Crampton, who anæsthetised the patient, are quite certain that the patient could not possibly have undergone what he did unless the shock had been reduced so strikingly by blocking the splanchnic nerves.

The last case I will quote is that of a man, aged 35 years, with seven years' history of chronic gastric ulcer, and also a history of a healed pulmonary tuberculous lesion. It was considered advisable to avoid a general anæsthetic in this man's case, hence the preliminary injections of morphine and scopolamine were given, and splanchnic analgesia induced without a general anæsthesia. Instead of doing the usual field block on this case, I did a paravertebral dorsal block from D6–D10 on both sides.

The abdomen was opened painlessly, and an ulcer causing stenosis of the pylorus was found; a partial gastrectomy was decided upon. The operation was continued for 1 hour 30 minutes without any anæsthetic, and during this time the duodenum had been divided, after great difficulty in separating it from the pancreas. The distal end of the duodenum was closed and the stomach turned over to the left with further division of the lesser omentum. When an attempt was made to bring up a loop of jejunum the patient felt pain when the lower end of the abdominal incision was handled, due, no doubt, to the fact that only the tenth nerve had been blocked, whereas it would have been wiser to have included the eleventh as well. Ether was therefore given till the end of the operation, which lasted 20 minutes longer. At the commencement the pulse-rate was 80, which rate was maintained throughout until the end when it was as low as 60, which it was when the patient left the table. He made a good recovery.

I think that these cases quoted show conclusively the undoubted advantages of this method of reducing shock and the amount of anæsthetic administered.

Advantages and Disadvantages of the Method.

I now propose to review the advantages claimed for this method, which has definitely improved the outlook for patients who have to undergo operations of a large magnitude on the upper abdomen.

1. *The Shock* in all cases has been conspicuous by its absence, as shown by the general appearance of the patients and by the pulse-rates. The general condition of the patients has been extraordinary, for instead of being patients who seem to have lost interest in themselves and their surroundings, they are so well that they rather resent the administration of rectal salines and such nursing as they must have. This is the only drawback to the method according to the sister in charge of these cases. A point in support of the absence of shock is the fact that no blood transfusion has been necessary since this new method has been used, whereas previously it was quite a common occurrence with difficult cases.

2. *Chest Complications.*—In this series of cases not one patient has developed any chest complications, and this includes one patient with a very definite chronic bronchitis, and one with healed tubercle. There is no doubt that prolonged inhalation anæsthesia is responsible for many fatal chest complications in abdominal operations, and this method affords an excellent way of reducing the amount of drug inhaled. In connexion with the respiratory system, it is worthy of note that by means of this technique the exaggerated respiratory movements seen with deep surgical inhalation anæsthesia are entirely done away with. These movements must of themselves be very fatiguing to the patients, as anyone can prove by performing as deep and rapid respiratory movements oneself. It is impossible to continue for more than a few moments, and yet patients may keep this up for one and a half to two hours.

3. *Post-operative Vomiting.*—This rarely occurs, or is so reduced that it scarcely distresses the patient. This has a great advantage, apart from the patient's comfort, in that suture lines both within the abdomen and in the abdominal wall are not strained.

4. *Cases Not Admitting of General Anæsthesia.*—Patients with weak hearts or diseased lungs or any other condition contra-indicating a general anæsthetic can be operated on with very reduced risks, and, in fact, a patient otherwise considered inoperable might well be saved by the use of this new method. It is early yet to discuss fully the advantages and disadvantages of splanchnic analgesia; the advantages I have set out, the disadvantages appear to me to be few: the careful practice and knowledge of anatomy required can scarcely be called a disadvantage. The fact that it is not always possible to be certain of a complete anæsthesia demands the presence of an anæsthetist apart from the surgeon, unless this technique be practised by one who is an anæsthetist. The time taken to perform the injections varies, of course, with the skill and experience of the person performing them, but they take 20 minutes to half an hour in a difficult case. These two points seem to me to be the only disadvantages of the

sagging of the spine. The first lumbar spine is identified, and at a point opposite this and 7 cm. external to it a cuticular wheal is raised with a fine needle, using 1 per cent. novocaine—this point is usually found to be on the lower border of the last rib. Through this cuticular wheal the 12 cm. needle is now introduced and pushed on a little upwards, and at an angle of about 45° to the median plane, until its point is felt to come into contact with the side of the body of the first lumbar vertebra. When this bony contact has been made, the needle is withdrawn to the subcutaneous tissues and the angle altered so that the needle now advances more to the front of the vertebra and the bony contact again made. This procedure is repeated until the needle is felt to slide by the edge of the body of the vertebra, when it is pushed 1 cm. further, and, after aspiration to see that the needle is not in the lumen of the vessel, 30 c.cm. of 1 per cent. novocaine are slowly injected.

The needle is again withdrawn to the subcutaneous tissues and its direction changed downwards towards the second lumbar vertebra, and the process repeated until 15 c.cm. of 1 per cent. solution can be deposited in the corresponding position to that vertebra. The result is that 45 c.cm., of 1 per cent. novocaine are left diffusing amongst the loose areolar tissue on the antero-lateral aspects of the *first* and *second* lumbar vertebræ, and therefore bathing the splanchnic nerves and cœliac plexus. It was from trial that it was found that by directing the needle upwards as well as forwards and inwards, which is a slight modification of Labat's technique, the needle in most cases comes into very close contact with the great splanchnic nerve itself. The patient is now turned on to the side just injected and the same procedure repeated on the other side, so that altogether 90 c.cm. of 1 per cent. novocaine are used for blocking the cœliac plexus.

The patients do not seem to feel much pain on the introduction of the needle, provided it is done gently, but it is always possible to infiltrate the track of the needle with some novocaine if it is thought desirable. In those cases in which a light ether narcosis is maintained from the commencement there is no question of difficulty in introducing the needles. The blocking of the cœliac plexus does not, of course, affect the sensibility of the abdominal wall, and therefore it is necessary to perform an abdominal field block as well before the abdomen can be opened, or as an alternative, a paravertebral dorsal block can be done. The patient, after the completion of the splanchnic injection, is now turned on to the back and the abdomen uncovered.

If the patient is conscious, cuticular wheals are raised at the point of the xiphisternum, at the outer border of the rectus where it crosses the costal margin, and at points along the linea semilunaris to just below the umbilicus on both sides. Through each of these wheals a needle 5 cm. long is introduced in turn and pushed into the rectus sheath, where about 2 c.cm. of the 1 per cent. solution is deposited at each point where the sheath is entered. The exact method is that the needle is first entered at right angles to the skin into the rectus sheath, and then more obliquely upwards and downwards, so that one point of skin entry is used for several points of entry into the rectus sheath. By the time that the last injections have been made the recti will be found to be perfectly relaxed, and when that is so the operation can be commenced.

Record of Cases.

I have carried out this procedure in 18 cases, and in every case there has been ample proof that the cœliac plexus has been blocked. In five of the cases the operations have been commenced and continued for some time without any general anæsthetic, and in two of the cases the operations have been completed without giving any general anæsthetic at all. By the time that the first three cases had been operated upon without general anæsthetic, it had been decided that the amount of ether required to keep the patients just unconscious from the beginning could not be very harmful, whereas it relieved the surgeon of the anxiety inseparable from performing a major operation on a conscious patient. For this reason all the subsequent cases have been done under a first-stage ether narcosis from the commencement, unless there has been some definite contra-indication to a general anæsthetic.

The first case on whom this new method was used was a man, aged 43 years, suffering with a chronic gastric ulcer and under Mr. Gordon-Taylor's care, as were all the patients described in this article. This patient was rather a nervous man, but the injections were carried out without causing him any undue discomfort. Without general anæsthesia the abdomen was opened, and the operation of partial gastrectomy proceeded with as far as division of both omenta and freeing the duodenum from the pancreas. When the clamp was passed under the duodenum and tightened, the patient became restless and ether was then given in just sufficient quantity to keep him asleep, and in this way the operation was completed. The man's pulse was 112 when he left the table, and at no time had his respirations been accelerated, which is invariably the case when traction is made on the viscera of the upper abdomen, which was convincing proof that the splanchnic nerves had been blocked. One advantage that this first case showed was the quietness of the respiratory movements; they were so small as to cause not the slightest inconvenience to the operator, a great contrast to the exaggerated respirations of an ether anæsthesia, and this point has been noticed in all subsequent cases. This patient had a most strikingly easy convalescence despite the fact that he was distinctly debilitated by his disease; he showed no evidence of shock or post-operative pain. A point worthy of note is that this patient is the first gastrectomy case of Mr. Gordon-Taylor's who has not had morphine on the night of the operation. The next morning he was sitting up in bed very well indeed, and the remainder of his convalescence was uneventful.

The second case was a man, aged 48 years, who, when the abdomen was opened, was found to have an inoperable carcinoma of the duodenum, for which a posterior gastro-jejunostomy was performed. The operation was completed without any general anæsthetic, and the patient subsequently said that he knew that something was being done, but there was "total absence of pain." The patient's pulse normally varied between 84 and 100, and at the end of the operation was 96. He had an uneventful convalescence. One hour after his return to bed he was talking as though he had not undergone any operation.

Another case was a private patient of Mr. Gordon-Taylor, who was given light ether anæsthesia throughout, and on whom a partial gastrectomy was performed. This was a very difficult case, the patient having had a posterior gastro-enterostomy performed one year previously by another surgeon, and a great number of adhesions had to be dealt with, which prolonged the operation. The operation lasted 2 hours and 20 minutes, but at the end of the time the patient's pulse was only 84, and subsequently it was never more than 82 during a rapid and easy convalescence. The patient volunteered that he felt better after this operation than he did after his first one.

The next case was a hospital patient, a man, aged 48 years, with a carcinoma of the stomach for which a partial gastrectomy was performed. The operation was continued as far as division of both omenta and the duodenum, but when the junction was commenced between the stomach and jejunum the patient appeared to feel pain, and therefore a mixture of ether and chloroform was given to finish the operation, the amount used being only 3 drachms. It is worthy of note that this patient had a chronic bronchitis, but he had no trouble from this during his convalescence, which he undoubtedly must have had had the operation been performed wholly under an inhalation anæsthesia. The pulse-rate after operation was 72; the operation lasted one hour. Three hours after the operation this man was asking if he might smoke, and on the following morning said he felt quite well enough to leave the hospital.

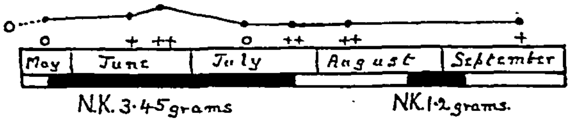
Two cases have been done that were not gastric cases, one a splenectomy and the other an ovariotomy.

The splenectomy was performed on a man, aged 26 years, suffering with splenic anæmia, light ether anæsthesia being given throughout. The patient's pulse-rate was 80 at the commencement of the operation, and remained at this rate throughout the first 20 minutes of the operation; nor did his respiratory-rate vary, even when the spleen, which was very large, was drawn out of the abdomen. When the splenic pedicle was clamped the pulse-rate rose to 92, but respirations did not alter, and at the end of the operation the pulse returned to 80. The patient made an uneventful recovery.

The ovariotomy was performed for a malignant ovarian cyst, which extended above the umbilicus and was associated with ascites. The patient was very ill, having just recovered from broncho-pneumonia, and a general anæsthetic was contra-indicated. In this case the splanchnic analgesia serological reactions. The serum from three patients was found to give a positive W.R. and a negative S.R. Several specimens were obtained from each of these patients, and while the S.R. was consistently negative the W.R. varied from positive to very weak positive, and in each case a negative W.R. was obtained once. The clinical diagnoses in these three cases were respectively chronic laryngitis, congenital deformity of nose, and persistent headaches.

The remaining 19 cases in this group are tabulated below with their diagnoses.

CHART 1.



Early primary case. Uninterrupted treatment.

3. *Cases in which No Records were Obtainable.*—This group contains 16 sera, two of which were positive to the W.R. and negative to the S.R., and 14 were negative to the W.R. and positive to the S.R.

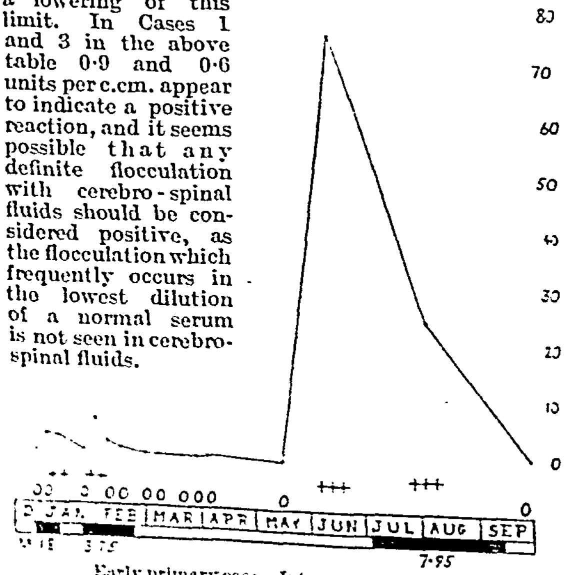
Cerebro-spinal Fluid.

The number of specimens of cerebro-spinal fluid examined was 81. In 77 instances the reactions were in agreement, 63 specimens being negative and 14 specimens positive. The remaining 4 specimens gave different results by the two methods.

Case.	Cerebro-spinal fluid.		Serum.		Diagnosis.
	W.R.	S.R.	W.R.	S.R.	
1	+ + +	0·9	0	0·0	Cerebro-spinal syphilis.
2	+ + +	0·0	+ + +	0·0	Retro-bulbar neuritis.
3	+	0·6	+ + +	33·6	Gummatous meningitis.
4	0	1·7	+ + +	65·6	Tabes dorsalis.

Dreyer and Ward[2] state that cerebro-spinal fluids which contain less than one Sigma unit per c.cm. are to be considered negative, but they consider that further experience may lead to a lowering of this limit. In Cases 1 and 3 in the above table 0·9 and 0·6 units per c.cm. appear to indicate a positive reaction, and it seems possible that any definite flocculation with cerebro-spinal fluids should be considered positive, as the flocculation which frequently occurs in the lowest dilution of a normal serum is not seen in cerebro-spinal fluids.

CHART 1A.



Early primary case. Interrupted treatment.

Flocculation and Complement Fixation in Early Primary Syphilis.

An attempt has been made to follow weekly the course of early primary cases which came under treatment before the serum reactions had become positive. The Sigma readings have been recorded in the form of curves and the W.R. results inserted at the bottom of the charts. Four curves have been selected which emphasise the well-known importance of adequate uninterrupted treatment with arsenobenzol preparations in the early stages of the disease.

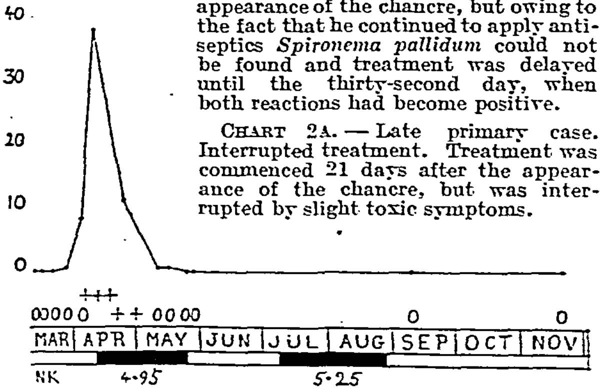
CHART 1.—Early primary case. Uninterrupted treatment. Treatment was commenced seven days after the appearance of the chancre. Small doses of neokharsivan were given without serious interruption for a relatively long period. The Sigma readings never rose to 1·5 units per c.cm. of serum, but there was frequent partial fixation of complement.

CHART 1A.—Early primary case. Interrupted treatment. Treatment was commenced 12 days after the appearance of the chancre. The patient did not attend for a fortnight during the first course of neokharsivan, and this interruption was followed by a rise in the Sigma curve which gradually came down when treatment was resumed. Owing to the appearance of toxic symptoms an unusually long interval elapsed before the commencement of the second course. During this period regular injections of mercury failed to prevent a sharp rise in the Sigma curve.

CHART 2.—Late primary case. Uninterrupted treatment. The patient came for treatment three days after the appearance of the chancre, but owing to the fact that he continued to apply antiseptics *Spironema pallidum* could not be found and treatment was delayed until the thirty-second day, when both reactions had become positive.

CHART 2A.—Late primary case. Interrupted treatment. Treatment was commenced 21 days after the appearance of the chancre, but was interrupted by slight toxic symptoms.

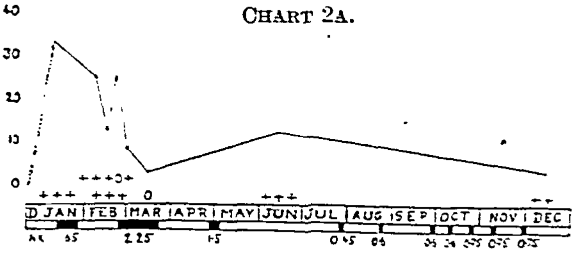
CHART 2.



Late primary case. Uninterrupted treatment.

The four cases had similar mercurial treatment and the only known factor which could contribute to the bad results in 1A and 2A was the interruption of arsenobenzol treatment.

CHART 2A.



Late primary case. Interrupted treatment.

Conclusions.

There is evidence that the S.R. is more delicate than the W.R. in well-treated cases of syphilis and in imperfectly treated cases of long standing, but it appears that reliance solely on either method may lead to a very small proportion of positive sera being missed. In the case of cerebro-spinal fluids the S.R. appears to have little advantage over the W.R. owing to the fact that in the latter reaction a much larger quantity of cerebro-spinal fluid than of serum can be used, whereas in the S.R. the quantities are the same.

From the limited number of primary cases examined it appears that the S.R. usually becomes positive before the W.R., but occasionally a positive W.R. is obtained first.

method, but they are so small that I think they are quite outweighed by the distinct benefit the patients undoubtedly derive from this method of nerve blocking.

I have had a special syringe for regional anæsthesia made for me by Messrs. Arnold and Sons.

In conclusion, I wish to express my thanks to Mr. Gordon-Taylor for suggesting this investigation to me, and for allowing me to use this method on his patients, and also for his permission to publish the cases concerned. I have also to thank the hon. anæsthetists of the Middlesex Hospital for their keenness in coöperating with me in the use of a new method.

FLOCCULATION AND COMPLEMENT FIXATION IN SYPHILIS.

BY E. W. TODD, M.D. CAMB., D.P.H.,
PATHOLOGIST TO THE VENEREAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

IN order to test the relative merits of flocculation and complement fixation for the sero-diagnosis of syphilis every suitable specimen of serum or cerebro-spinal fluid sent to the pathological department of St. Bartholomew's Hospital for the Wassermann reaction (W.R.) during the past year has been examined by both methods. The sera included those obtained from the venereal department as well as those from the wards and out-patient department of the hospital. In carrying out the W.R. the technique described by Fildes[1] was followed. The results were recorded as (1) positive +++, complete inhibition of hæmolysis; (2) weak positive ++, slight hæmolysis; (3) very weak positive +, slight inhibition of hæmolysis. The flocculation test employed was the Sigma reaction (S.R.) detailed by Dreyer and Ward.[2] The heart extracts used in the S.R. were kindly supplied from Oxford with suspension factors determined. The number of specimens examined by both methods was 2092, comprising 2011 sera and 81 cerebro-spinal fluids.

Sera: Cases in which the Reactions Agreed.

The results obtained by the two methods were the same in 1755 specimens (87·3 per cent. coincidence)—namely, 1175 negative reactions and 580 positive reactions. The number of positive reactions includes partially positive W.R. results and S.R. readings which indicated 1·5 units per c.cm. of serum.

Sera: Cases in which the Reactions did Not Agree.

In 250 instances the reactions were not in agreement and reference to the clinical records of these cases led to their classification in three groups.

1. *Cases with Definite Evidence of Syphilis.*—Under this heading are grouped all cases which at an earlier date gave a positive reaction by both methods, cases which had definite clinical syphilis, including primary lesions in which *Spironema pallidum* was found, and cases of tabes dorsalis and G.P.I. A less definite class has also been included—namely, those patients who stated that they had been infected with syphilis many years ago. The majority of cases in this group had received some form of anti-syphilitic treatment. The results of the two reactions were as follows:—

W.R. positive and S.R. negative in	31	cases.
W.R. negative and S.R. positive in	176	,,
	207	

A considerable modification of these figures is brought about if the number of persons whose blood was examined is substituted for the actual number of specimens, as in some cases serum from the same patient was examined several times at intervals, varying from a few days to a year. The following figures refer to patients and not to the number of specimens examined.

It will be seen that the results of the S.R. were in agreement with the clinical data in 86 per cent. of this group of cases.

One exam. of serum	73	W.R. pos. and S.R. neg.	15
More than one exam. of serum	52	W.R. neg. and S.R. pos.	108
		Results variable	2
	125		125

With two exceptions, the discrepancies between the two reactions were found each time a specimen of the patient's serum was examined. Seven cases gave a positive or partially positive W.R. and a negative S.R., but none of them consistently gave a fully positive W.R. In those cases which were examined on one occasion there was one in which the W.R. was fully positive and the S.R. negative. Forty-three cases on re-examination were consistently positive to the S.R. and negative to the W.R. The two exceptions were both well-treated cases and the results obtained were as follows:—

		Units per c.cm.
	Case 1.	
First exam. ..	W.R. negative ..	S.R. 1·7
Second ,, ..	,, very weak pos. + ..	,, 1·3
	Case 2.	
First ,, ..	W.R. negative ..	,, 1·5
Second ,, ..	,, weak pos. ++ ..	,, 1·3
Third ,, ..	,, negative ..	,, 1·5

In both cases the reactions were becoming negative after treatment, and the results are, therefore, in practical agreement as a border-line reaction is indicated by both methods.

2. *Cases where Evidence of Syphilitic Infection was Doubtful.*—Thirty-three specimens of serum derived from 24 patients are included in this group. The discrepancy between the W.R. and S.R. in one case was presumably due to an error in technique, as on re-examination the reactions were in agreement. Another case in which a quantitative W.R. was strongly positive was remarkable in the serum exhibiting an unusually high inhibition zone which, at first, caused the S.R. to be considered negative when it was really strongly positive. A specimen of this serum was sent to Dr. H. K. Ward, who reported as follows:—

"The following were the readings after 22 hours' incubation:—

Dilution of Serum.

$\frac{1}{1\cdot25}$	$\frac{1}{2\cdot5}$	$\frac{1}{5\cdot2}$	$\frac{1}{13\cdot1}$	$\frac{1}{26\cdot4}$	$\frac{1}{53}$	$\frac{1}{106}$	$\frac{1}{265}$	$\frac{1}{530}$	$\frac{1}{1060}$	$\frac{1}{2120}$	$\frac{1}{5300}$	$\frac{1}{10600}$
Reading.												
S+	tr+	tr	tr?	0	tr?	tr?	tr	tr+	T	T−	tr?	0

The flocculation in the fore zone was not typical in that there was no clearing commensurate with the degree of flocculation."

The number of Sigma units per c.cm. of this serum was 2865. The patient was suffering from nephritis and there was no evidence of syphilis other than the

Prescription of Diets.

This is still the great stumbling-block to many practitioners. They recognise that in no two instances will the course of dieting, if correctly applied, be the same; the amounts of carbohydrate, protein, and fat in the diet will vary according to the several defects of metabolism present. Furthermore, if insulin be given, the distribution of the carbohydrate, protein, and fat over the 24 hours must be correlated with the time or times of its administration and the dosage. The patient's likes and dislikes in the matter of food also demand attention. It is clearly impossible to solve the problem by constructing 24-hour diet-charts to meet every contingency. On the other hand, one may daily, or from time to time, prescribe the meals in detail, so as to conform to the changes in metabolism and the needs of the patient; this would be ideal for

DIAGNOSIS AND TREATMENT OF DIABETES MELLITUS IN HOSPITAL AND GENERAL PRACTICE.

BY EDWIN G. B. CALVERT, M.D. BELF.,
M.R.C.P. LOND., D.P.H.,
ASSISTANT, MEDICAL CLINICAL UNIT, ST. MARY'S HOSPITAL, W.

(Concluded from p. 1314.)

Food Values.

THE following list of food values (Table I.) has been compiled from the U.S. Government Reports (1906 and 1913), and the works of Joslin, Atwater and Bryant, Street, McKillop, and others. To facilitate dieting, the value of the foods when ready for use are alone given. In view of the fact that the various authorities often differ a little in their analyses, the figures for certain foodstuffs have been selected, within the range of variation, so as to permit of the formation of groups of equivalents. The values, which can never be more than approximate, are sufficiently accurate for practical purposes. The simplicity and usefulness of the table from the standpoint of doctor, nurse, and patient are obvious.

The immediate aim of dietetic treatment is to provide the patient with sufficient nourishment for health, and at the same time keep the urine free from sugar and any appreciable amount of acetone bodies.

TABLE I.

Grammes of carbohydrate, protein, and fat in 1 oz. of the following (ready for consumption):—

1 oz. of:	C.(g.)	P.(g.)	F.(g.)
"x" Beef: rump, loin, tongue, lean (cooked). Chicken (cooked). Herring (cooked). Liver (cooked). Kidney (cooked). Salmon (boiled)	—	6	3
"y" Mutton or lamb: leg or shoulder (boiled or roast). Veal (cooked). Turkey (cooked). Sausage (Bologna, Frankfort). Sardines (tinned). Salmon (tinned). Ham, lean (smoked or boiled)	—	5	5
"z" Beef: fat (cooked). Mutton or lamb, moderately fat (cooked). Ham, moderately fat (smoked or boiled). Pork: loin, ribs, or shoulder (cooked). Sausage, pork. Beef (corned)	—	4	9
Cheese: Cheddar, Cheshire, Roquefort, Swiss, Cream, Stilton	—	7	9
Bran biscuits (Callard and Co.)	—	—	—
Bacon, fat retained (fried)..	—	4	16
1 egg (=2 oz.; half of the protein and all the fat are in the yolk) .. .. .. =	—	6	6
Fish, white (boiled)	—	5	—
Clear soup or bovril or beef-tea (6–10 oz.)..	—	1	—
"Akoll" biscuits (Huntley and Palmer): each biscuit .. .. =	0·1	2	1
Butter or Margarine .. .. .. Lard .. .. Salad Oil	—	—	24
(p) Bread (brown or white)	13·2	2·4	—

(s) Sago (cooked, using little milk). Semolina (ditto). Farola (ditto)	3·3	0·6	—
Almonds, brazil nuts, walnuts	3	5	17
Milk (whole)	1·4	1	1
,, (skimmed)	1·4	1	0·1
Cream (thin), 1 teaspoonful .. .. =	—	—	0·5
,, (thick), ,, ... =	—	—	1·5

Note.—(p) = 2 (q) = 3(r) = 4(s).

Vegetables and Fruits. (Based on Joslin's Tables.)

—	1 oz. contains approx.:		
	C.(g.)	P.(g.)	F.(g.)
GROUP I. Vegetables— Tomatoes, lettuce, watercress, endive, cabbage, celery, spinach, marrow, cauliflower, cucumber, sea-kale, Brussels sprouts, mushrooms, radishes, leeks, French beans, asparagus, broccoli, turnips, onions .. .. Fruits— Rhubarb, grape fruit	1	0·3	—
GROUP III. Vegetables— Green peas, carrots, beets, artichokes, water-melon .. .. Fruits— Oranges, fresh pineapple, peaches, apricots, strawberries, raspberries, cranberries, gooseberries. Apples and pears vary from 3-5 g. carboh.	3	0·3	—
GROUP V. Grapes, figs, plums, prunes, bananas (also canned pears, peaches, and pineapple)..	5	0·3	—

Note.—1. Values given are for the fresh article; if cooked, a little over-weight is allowed. 2. If boiled a second time, and in a change of water, half to two-thirds of these values should be taken. 3. The groups are labelled according to the amount of carbohydrate.

The amount of acetone bodies is considered appreciable when even a slight ferric chloride reaction is obtained; to avoid fallacy, care must be taken that the patient is not taking drugs, particularly those of the phenol class.

Some cases clear up in a remarkably short time on, first of all, withdrawing most of the fat in the diet and subsequently reducing the carbohydrate and protein, especially the former, to a point at which the urine ceases to be abnormal. The more usual method is to begin by fasting the patient—only clear soup, beef-tea, bovril, and unsweetened tea or coffee (without milk), or lemonade being allowed. One or two days of this treatment often suffices. If, at the end of the second day, sugar is still present it is advisable to allow a little nourishment for one or two days—mainly protein and carbohydrate, the latter in the form of group 1 vegetables, e.g., a diet containing about 5–10 g. carbohydrate, 20–25 g. protein, and 5–10 g. fat with tea, coffee, &c., "ad lib." as before. A further one or two days of fasting may still be required, but this is unusual. Should sugar even then be present, it is advisable steadily to increase the diet over a period of five or six days until, say, roughly half the requisite number of calories are being given; at this stage it is better to order rather more protein than fat. Another attempt to render the urine sugar-free by fasting may now be made. If unsuccessful, the patient ought to be given the diet which seems to have the most suitable distribution of foodstuffs and contains enough calories for health. Although the glycosuria, usually reduced in amount, continues in such cases, there is often considerable improvement in the general condition. Of course, insulin might have been used at any stage in the treatment to abolish the glycosuria and restore the blood-sugar to normal. When at all possible, insulin should be given to these patients, also to those in whom any considerable degree of ketonuria persists after the maximum of carbohydrate tolerance has been established.

Cases rendered sugar-free by fasting are given a gradually increasing dietary, built up on the lines just indicated, with a fast on every seventh day, until in the course of two or three weeks adequate nourishment is being taken. Should glycosuria reappear at any time, it is corrected by fasting for a day or so, and the scale of diets then continued. If it be impossible to give the required number of calories without glycosuria recurring, then again one must decide whether the glycosuria should be allowed to continue or whether insulin should be employed.

Prescription of Diets.

This is still the great stumbling-block to many practitioners. They recognise that in no two instances will the course of dieting, if correctly applied, be the same; the amounts of carbohydrate, protein, and fat in the diet will vary according to the several defects of metabolism present. Furthermore, if insulin be given, the distribution of the carbohydrate, protein, and fat over the 24 hours must be correlated with the time or times of its administration and the dosage. The patient's likes and dislikes in the matter of food also demand attention. It is clearly impossible to solve the problem by constructing 24-hour diet-charts to meet every contingency. On the other hand, one may daily, or from time to time, prescribe the meals in detail, so as to conform to the changes in metabolism and the needs of the patient; this would be ideal for

Note.—(*a*) The figures underneath each meal = g. C., P., and F., in this order, followed by the total number of calories in the meal. (*b*) B., L., T., S., and D. are described in the text. (*c*) All food shown above is ready for consumption. (*d*) Bran biscuits may be obtained from Messrs. Callard and Co., Regent-street, London; "Akoll" biscuits from Messrs. Huntley and Palmer, Reading.

DIAGNOSIS AND TREATMENT OF DIABETES MELLITUS IN HOSPITAL AND GENERAL PRACTICE.

By EDWIN G. B. CALVERT, M.D. Belf.,
M.R.C.P. Lond., D.P.H.,
ASSISTANT, MEDICAL CLINICAL UNIT, ST. MARY'S HOSPITAL, W.

(*Concluded from p. 1314.*)

Food Values.

The following list of food values (Table I.) has been compiled from the U.S. Government Reports (1906 and 1913), and the works of Joslin, Atwater and Bryant, Street, McKillop, and others. To facilitate dieting, the value of the foods when ready for use are alone given. In view of the fact that the various authorities often differ a little in their analyses, the figures for certain foodstuffs have been selected, within the range of variation, so as to permit of the formation of groups of equivalents. The values, which can never be more than approximate, are sufficiently accurate for practical purposes. The simplicity and usefulness of the table from the standpoint of doctor, nurse, and patient are obvious.

The immediate aim of dietetic treatment is to provide the patient with sufficient nourishment for health, and at the same time keep the urine free from sugar and any appreciable amount of acetone bodies.

TABLE I.

Grammes of carbohydrate, protein, and fat in 1 oz. of the following (ready for consumption):—

1 oz. of:	C.(g.)	P.(g.)	F.(g.)
"x" Beef: rump, loin, tongue, lean (cooked). Chicken (cooked). Herring (cooked). Liver (cooked). Kidney (cooked). Salmon (boiled)	—	6	3
"y" Mutton or lamb: leg or shoulder (boiled or roast). Veal (cooked). Turkey (cooked). Sausage (Bologna, Frankfort). Sardines (tinned). Salmon (tinned). Ham, lean (smoked or boiled)	—	5	5
"z" Beef: fat (cooked). Mutton or lamb, moderately fat (cooked). Ham, moderately fat (smoked or boiled). Pork: loin, ribs, or shoulder (cooked). Sausage, pork. Beef (corned)	—	4	9
Cheese: Cheddar, Cheshire, Roquefort, Swiss, Cream, Stilton	—	7	9
Bran biscuits (Callard and Co.)	—	—	—
Bacon, fat retained (fried)..	—	4	16
1 egg (=2 oz.; half of the protein and all the fat are in the yolk) .. .. .. =	—	6	6
Fish, white (boiled)	—	5	—
Clear soup or bovril or beef-tea (6–10 oz.)..	—	1	—
"Akoll" biscuits (Huntley and Palmer): each biscuit .. .. =	0·1	2	1
Butter or Margarine .. .. .. Lard .. .. Salad Oil	—	—	24
(p) Bread (brown or white)	13·2	2·4	—
(q) Rice (cooked, using a moderate amount of milk). Macaroni (ditto). Tapioca (ditto).. ..	6·6	1·2	—
(r) Potato (boiled). Oatmeal porridge, moderately thin	4·4	0·8	—
(s) Sago (cooked, using little milk). Semolina (ditto). Farola (ditto)	3·3	0·6	—
Almonds, brazil nuts, walnuts	3	5	17
Milk (whole)	1·4	1	1
,, (skimmed)	1·4	1	0·1
Cream (thin), 1 teaspoonful .. .. =	—	—	0·5
,, (thick), ,, ... =	—	—	1·5

Note.—(p) = 2 (q) = 3(r) = 4(s).

Vegetables and Fruits. (Based on Joslin's Tables.)

—	1 oz. contains approx.:		
	C.(g.)	P.(g.)	F.(g.)
GROUP I.			
Vegetables— Tomatoes, lettuce, watercress, endive, cabbage, celery, spinach, marrow, cauliflower, cucumber, sea-kale, Brussels sprouts, mushrooms, radishes, leeks, French beans, asparagus, broccoli, turnips, onions .. .. Fruits— Rhubarb, grape fruit	1	0·3	—
GROUP III.			
Vegetables— Green peas, carrots, beets, artichokes, water-melon .. .. Fruits— Oranges, fresh pineapple, peaches, apricots, strawberries, raspberries, cranberries, gooseberries. Apples and pears vary from 3–5 g. carboh.	3	0·3	—
GROUP V.			
Grapes, figs, plums, prunes, bananas (also canned pears, peaches, and pineapple)..	5	0·3	—

Note.—1. Values given are for the fresh article; if cooked, a little over-weight is allowed. 2. If boiled a second time, and in a change of water, half to two-thirds of these values should be taken. 3. The groups are labelled according to the amount of carbohydrate.

The amount of acetone bodies is considered appreciable when even a slight ferric chloride reaction is obtained; to avoid fallacy, care must be taken that the patient is not taking drugs, particularly those of the phenol class.

Some cases clear up in a remarkably short time on, first of all, withdrawing most of the fat in the diet and subsequently reducing the carbohydrate and protein, especially the former, to a point at which the urine ceases to be abnormal. The more usual method is to begin by fasting the patient—only clear soup, beef-tea, bovril, and unsweetened tea or coffee (without milk), or lemonade being allowed. One or two days of this treatment often suffices. If, at the end of the second day, sugar is still present it is advisable to allow a little nourishment for one or two days—mainly protein and carbohydrate, the latter in the form of group 1 vegetables, e.g., a diet containing about 5–10 g. carbohydrate, 20–25 g. protein, and 5–10 g. fat with tea, coffee, &c., "ad lib." as before. A further one or two days of fasting may still be required, but this is unusual. Should sugar even then be present, it is advisable steadily to increase the diet over a period of five or six days until, say, roughly half the requisite number of calories are being given; at this stage it is better to order rather more protein than fat. Another attempt to render the urine sugar-free by fasting may now be made. If unsuccessful, the patient ought to be given the diet which seems to have the most suitable distribution of foodstuffs and contains enough calories for health. Although the glycosuria, usually reduced in amount, continues in such cases, there is often considerable improvement in the general condition. Of course, insulin might have been used at any stage in the treatment to abolish the glycosuria and restore the blood-sugar to normal. When at all possible, insulin should be given to these patients, also to those in whom any considerable degree of ketonuria persists after the maximum of carbohydrate tolerance has been established.

Cases rendered sugar-free by fasting are given a gradually increasing dietary, built up on the lines just indicated, with a fast on every seventh day, until in the course of two or three weeks adequate nourishment is being taken. Should glycosuria reappear at any time, it is corrected by fasting for a day or so, and the scale of diets then continued. If it be impossible to give the required number of calories without glycosuria recurring, then again one must decide whether the glycosuria should be allowed to continue or whether insulin should be employed.

Prescription of Diets.

This is still the great stumbling-block to many practitioners. They recognise that in no two instances will the course of dieting, if correctly applied, be the same; the amounts of carbohydrate, protein, and fat in the diet will vary according to the several defects of metabolism present. Furthermore, if insulin be given, the distribution of the carbohydrate, protein, and fat over the 24 hours must be correlated with the time or times of its administration and the dosage. The patient's likes and dislikes in the matter of food also demand attention. It is clearly impossible to solve the problem by constructing 24-hour diet-charts to meet every contingency. On the other hand, one may daily, or from time to time, prescribe the meals in detail, so as to conform to the changes in metabolism and the needs of the patient; this would be ideal for

Note.—(*a*) The figures underneath each meal = g. C., P., and F., in this order, followed by the total number of calories in the meal. (*b*) B, L, T, S, and D are described in the text. (*c*) All food shown above is ready for consumption. (*d*) Bran biscuits may be obtained from Messrs. Callard and Co., Regent-street, London; "Akoll" biscuits from Messrs. Huntley and Palmer, Reading.

DIAGNOSIS AND TREATMENT OF DIABETES MELLITUS IN HOSPITAL AND GENERAL PRACTICE.

By EDWIN G. B. CALVERT, M.D. Belf., M.R.C.P. Lond., D.P.H.,
ASSISTANT, MEDICAL CLINICAL UNIT, ST. MARY'S HOSPITAL, W.

(*Concluded from p. 1314.*)

Food Values.

The following list of food values (Table I.) has been compiled from the U.S. Government Reports (1906 and 1913), and the works of Joslin, Atwater and Bryant, Street, McKillop, and others. To facilitate dieting, the value of the foods when ready for use are alone given. In view of the fact that the various authorities often differ a little in their analyses, the figures for certain foodstuffs have been selected, within the range of variation, so as to permit of the formation of groups of equivalents. The values, which can never be more than approximate, are sufficiently accurate for practical purposes. The simplicity and usefulness of the table from the standpoint of doctor, nurse, and patient are obvious.

The immediate aim of dietetic treatment is to provide the patient with sufficient nourishment for health, and at the same time keep the urine free from sugar and any appreciable amount of acetone bodies.

Table I.

Grammes of carbohydrate, protein, and fat in 1 oz. of the following (ready for consumption):—

1 oz. of:	C.(g.)	P.(g.)	F.(g.)
"x" Beef: rump, loin, tongue, lean (cooked). Chicken (cooked). Herring (cooked). Liver (cooked). Kidney (cooked). Salmon (boiled)	—	6	3
"y" Mutton or lamb: leg or shoulder (boiled or roast). Veal (cooked). Turkey (cooked). Sausage (Bologna, Frankfort). Sardines (tinned). Salmon (tinned). Ham, lean (smoked or boiled)	—	5	5
"z" Beef: fat (cooked). Mutton or lamb, moderately fat (cooked). Ham, moderately fat (smoked or boiled). Pork: loin, ribs, or shoulder (cooked). Sausage, pork. Beef (corned)	—	4	9
Cheese: Cheddar, Cheshire, Roquefort, Swiss, Cream, Stilton	—	7	9
Bran biscuits (Callard and Co.)	—	—	—
Bacon, fat retained (fried)..	—	4	16
1 egg (=2 oz.; half of the protein and all the fat are in the yolk) .. .. .. =	—	6	6
Fish, white (boiled)	—	5	—
Clear soup or bovril or beef-tea (6–10 oz.)..	—	1	—
"Akoll" biscuits (Huntley and Palmer): each biscuit .. .. =	0·1	2	1
Butter or Margarine .. .. .. Lard .. .. Salad Oil	—	—	24
(p) Bread (brown or white)	13·2	2·4	—
(q) Rice (cooked, using a moderate amount of milk). Macaroni (ditto). Tapioca (ditto).. ..	6·6	1·2	—
(r) Potato (boiled). Oatmeal porridge, moderately thin	4·4	0·8	—
(s) Sago (cooked, using little milk). Semolina (ditto). Farola (ditto)	3·3	0·6	—
Almonds, brazil nuts, walnuts	3	5	17
Milk (whole)	1·4	1	1
,, (skimmed)	1·4	1	0·1
Cream (thin), 1 teaspoonful .. .. =	—	—	0·5
,, (thick), ,, ... =	—	—	1·5

Note.—(p) = 2 (q) = 3(r) = 4(s).

Vegetables and Fruits. (*Based on Joslin's Tables.*)

—	1 oz. contains approx.:		
	C.(g.)	P.(g.)	F.(g.)
Group I. Vegetables— Tomatoes, lettuce, watercress, endive, cabbage, celery, spinach, marrow, cauliflower, cucumber, sea-kale, Brussels sprouts, mushrooms, radishes, leeks, French beans, asparagus, broccoli, turnips, onions .. .. Fruits— Rhubarb, grape fruit	1	0·3	—
Group III. Vegetables— Green peas, carrots, beets, artichokes, water-melon .. .. Fruits— Oranges, fresh pineapple, peaches, apricots, strawberries, raspberries, cranberries, gooseberries. Apples and pears vary from 3–5 g. carboh.	3	0·3	—
Group V. Grapes, figs, plums, prunes, bananas (also canned pears, peaches, and pineapple)..	5	0·3	—

Note.—1. Values given are for the fresh article; if cooked, a little over-weight is allowed. 2. If boiled a second time, and in a change of water, half to two-thirds of these values should be taken. 3. The groups are labelled according to the amount of carbohydrate.

The amount of acetone bodies is considered appreciable when even a slight ferric chloride reaction is obtained; to avoid fallacy, care must be taken that the patient is not taking drugs, particularly those of the phenol class.

Some cases clear up in a remarkably short time on, first of all, withdrawing most of the fat in the diet and subsequently reducing the carbohydrate and protein, especially the former, to a point at which the urine ceases to be abnormal. The more usual method is to begin by fasting the patient—only clear soup, beef-tea, bovril, and unsweetened tea or coffee (without milk), or lemonade being allowed. One or two days of this treatment often suffices. If, at the end of the second day, sugar is still present it is advisable to allow a little nourishment for one or two days—mainly protein and carbohydrate, the latter in the form of group 1 vegetables, e.g., a diet containing about 5–10 g. carbohydrate, 20–25 g. protein, and 5–10 g. fat with tea, coffee, &c., "ad lib." as before. A further one or two days of fasting may still be required, but this is unusual. Should sugar even then be present, it is advisable steadily to increase the diet over a period of five or six days until, say, roughly half the requisite number of calories are being given; at this stage it is better to order rather more protein than fat. Another attempt to render the urine sugar-free by fasting may now be made. If unsuccessful, the patient ought to be given the diet which seems to have the most suitable distribution of foodstuffs and contains enough calories for health. Although the glycosuria, usually reduced in amount, continues in such cases, there is often considerable improvement in the general condition. Of course, insulin might have been used at any stage in the treatment to abolish the glycosuria and restore the blood-sugar to normal. When at all possible, insulin should be given to these patients, also to those in whom any considerable degree of ketonuria persists after the maximum of carbohydrate tolerance has been established.

Cases rendered sugar-free by fasting are given a gradually increasing dietary, built up on the lines just indicated, with a fast on every seventh day, until in the course of two or three weeks adequate nourishment is being taken. Should glycosuria reappear at any time, it is corrected by fasting for a day or so, and the scale of diets then continued. If it be impossible to give the required number of calories without glycosuria recurring, then again one must decide whether the glycosuria should be allowed to continue or whether insulin should be employed.

These mild symptoms usually disappear rapidly after giving a hot drink, or a portion of the food belonging to the next meal. The patient should not be encouraged to have immediate recourse to sugar on such slight provocation. It is most important, however, that sugar be always at hand in case of emergency. If the above measures do not suffice, or if the symptoms be more marked from the start, then ½–2 oz. glucose or cane sugar must be given at once by the mouth. Recovery takes place within 10–15 minutes. Should unconsciousness have supervened, or the patient be unable to swallow, ¾–1 c.cm. of 1 in 1000 adrenalin, or ¾–1 c.cm. pituitrin, injected hypodermically, will practically always bring the patient round sufficiently within five minutes to take sugar by the mouth. If these remedies are not available, or if they do not prove effective, sugar must without delay be given intravenously. From 20 to 100 c.cm. of a 20 per cent. solution of glucose may be required. If the intravenous route fails the sugar should be injected into the subcutaneous tissues. Brandy and hot drinks are of value when consciousness has been restored. With ordinary care, however, mishaps of this nature do not occur.

Any patient who is having insulin and going about his work should as a precaution, always carry in his pocket about half-a-dozen lumps of sugar; this is really imperative if the dose be 20 units or over.

Correlation of the Diet and the Dose of Insulin.—Some physicians begin treatment by fasting the patient for a few days, or by fasting plus insulin before proceeding gradually to build up a suitable diet with the help of this remedy. The majority, however, employ the simpler method of putting the patient immediately on a diet calculated to supply his wants, and then endeavouring to restore normal metabolism by cautiously increasing the daily dose of insulin, which at first is a small one. Each method has its points. In the first one the blood-sugar is more rapidly controlled but a sufficient dietary is more slowly reached, in the second a full dietary is given from the beginning, but the decline of the hyperglycæmia is relatively slow. Further, as regards the latter, it cannot be considered the best practice in some cases, especially those in which debility is marked and the appetite poor, suddenly to throw upon the system the burden of a comparatively large meal that cannot be properly utilised. Personally, I favour an intermediate course, in which the patient is started on a diet containing roughly two-thirds of his calorie requirements and the dose of insulin gradually increased until satisfactory results are obtained. From this point a diet, sufficient for health, is steadily built up, care being taken meanwhile that the desired insulin effect is maintained by regulation of the dose. Circumstances and common sense, however, will decide in any particular instance whether at first a full diet or a fraction of it is the more applicable. As the procedure is essentially the same in both, the method of using the initial full diet will, for sake of simplicity, only be described.

The duration of the action of insulin depends partly on the size of the dose and partly on the severity of the disease. It may, for practical purposes, be put at four to eight, or roughly six, hours. The dose or doses should be so arranged that at least the bulk of the day's food is covered thereby; this applies particularly to the carbohydrate portion. In a case of any severity it is better to begin with two injections per diem; sometimes three may be necessary. As improvement takes place it may be possible to arrange the dietary so that most of it comes under the influence of a single dose without the return of symptoms. Continued progress may permit of further reduction of insulin, perhaps even its complete withdrawal occasionally. When two doses are to be given it is best to order two major and one or two minor meals in the 24 hours—e.g., a relatively large breakfast and lunch at, say, 9 A.M. and 2 P.M.; a moderately small tea at 5 o'clock, and a very light supper at 8 o'clock; bovril may be taken at 11.30 A.M. When patients are at work and away from home during the lunch-hour, it will probably be found more convenient to arrange the diet so that little is taken at midday, a meal equivalent to lunch being allowed at tea-time on the patient's return home. Insulin, in initial doses of 5 units, is given half an hour before the two larger meals; in severe cases bigger doses—e.g., 10 units—may be required. The patient should rest in bed at the beginning of treatment, or at least he should stay within doors. The 24-hour urine should be tested daily for sugar and diacetic acid. If all goes well the insulin may be increased, say, at the rate of 5 units daily, or only every second, third, or fourth day, first of all adding to the dose before lunch and then to the one before breakfast. The immediate object in view is to cause a gradual disappearance of sugar from the urine. Any single dose ought not to exceed 30 units. The effect of insulin in controlling hyperglycæmia is enhanced by reducing the carbohydrate intake and vice versa. When only one dose is indicated I find it is best to order a very light breakfast, a lunch containing almost half of the food for the 24 hours, a tea three and a half hours later, containing about one-third of the diet, and a light supper four hours afterwards; the injection is given before lunch. If insulin be discontinued, the three or four meals should be made nearly equal in food value and the interval longer than usual.

If glycosuria has been so reduced that only a small amount of sugar remains, it is valuable in the absence of blood-sugar estimations, and especially when large doses of insulin are being used, to test for sugar in the urine collected over the two hours preceding each injection. A sugar-free specimen should be an indication to proceed more carefully; it may even be advisable slightly to reduce the dosage if this be large. A 24-hour specimen free from sugar means that much has been accomplished for the patient, and the practitioner may be content to adjust the dose of insulin so that the condition just borders on glycosuria. If, however, he would secure the best results he must try to reduce the blood-sugar to a normal level. This may be effected safely by continuing the dose which had gradually freed the urine of sugar, strict watch being kept for the initial symptoms of hypoglycæmia. If none of these present themselves within four to five days, then the dose should be increased by a few units, say, every third or fourth day, until such symptoms just begin to appear. There is no danger in this procedure if the patient has been taught how to recognise and deal with the condition. The optimum dose is a little less than that which caused the symptoms. The latter may reappear as tolerance for carbohydrate improves; if so, more insulin is withdrawn.

It is, therefore, possible to treat diabetes quite satisfactorily without blood-sugar estimations, and by proceeding on these lines even the busiest practitioner can readily employ insulin with every prospect of success. The blood-tests, however, permit of a more rapid and more accurate adjustment of dosage, and consequently of an earlier and more effective rest for the pancreas. For this purpose estimations are best carried out before the first meal of the day, and three to hour hours after the injections.

The following is a brief example of the early part of the treatment advocated above:—

Patient, aged 30 years, weight 120 lb., under-nourished, urinary sugar 4 per cent., moderate degree of ketonuria. "fasting" blood-sugar in the morning 0·25 per cent., blood-sugar two hours after 20 g. glucose 0·35 per cent.

Calorie requirement (resting or at light work) = 120 × 13 = 1560 calories. A little in excess of this is ordered because the patient appears to be under-nourished. The diet as shown in Table IV. was therefore allowed.

Five units of insulin were given before breakfast and before lunch and the dose gradually increased, as described, until glycosuria was abolished and the sugar-content of the blood lowered to within normal

the patient, but calculations, &c., make it laborious for the doctor.

I have adopted a scheme of dieting which, used in conjunction with the foregoing table of "food values," has proved of great help in treating patients, both in and out of hospital. (Table II.) Menus of a number of so-called "basal" breakfasts (B_1, B_2, B_3, &c.), lunches (L_1, L_2, &c.), teas (T_1, &c.), and suppers (S_1, &c.) have been drawn up; these contain varying quantities of carbohydrate, protein, and fat. (See "System of Diets.") A dietary consisting of B_1, L_1, T_1, S_1 constitutes a 24-hour fast; for convenience the fasting diet may be referred to as D_1. Similarly, one may speak of D_2, D_3, D_4, &c.; the latter, however, are not intended to be regarded as whole-day diets, though *some* may be used as such. Of the basal breakfasts, lunches, &c., any number may be employed. Personally, I make use of 14 sets, but owing to lack of space only ten are shown. The latter will probably suffice, however, in most cases—at any rate, they serve to illustrate the principle of the method. Now the number of different 24-hour diets (consisting of B, L, T, S) that can be selected from these sets $= 10^4 = 10{,}000$. A certain proportion of these would never be used, but taking into account the varied distribution of the diet with insulin therapy as described later, and the fact that lunches and suppers are interchangeable, also in some instances the breakfast and teas, I should think that 50 per cent. of them are capable of finding an application at some time or other.

The following is an example of a prescription: B_6, L_8, T_4, S_7. In the formula B_6, L_8, T_4, L_6, the L_6 is being used as a supper. *Additional amounts of carbohydrates, protein, and fat may be added to these basal meals without involving more than a momentary calculation.* For out-patient work or in general practice it is convenient to have the various meals printed on separate slips of paper—the patient is simply handed the requisite B, L, T, S slips and a printed list of the groups of foodstuffs, while the formula, with its values, is recorded in the notes of the case (Table III.).

TABLE III.

—	C.	P.	F.	Calories.
B_6 .. =	10·4	20·6	24·0	= 340·0
L_8 .. =	12·9	36·5	70·5	= 832·1
T_4 .. =	2·9	11·1	6·5	= 114·5
S_7 .. =	8·5	28·5	25·5	= 377·5
Total =	34·7	96·7	126·5	= 1664·1

Insulin Treatment.

We now come to the class of case—Class A, previously described—in which insulin is of outstanding value. In such, insulin treatment should be commenced without delay, especially in A (1), A (3), and A (4). The insulin, given hypodermically, compensates for the deficiency of pancreatic hormone, and in this way the metabolism of carbohydrate and fat is, more or less, restored to normal. As already stated, the aim of treatment should be to rest the islet cells as much as possible by keeping the blood-sugar concentration at, or near, the fasting level, and simultaneously to provide nourishment sufficient for the needs of the body. Those cells which are not irreparably damaged, or those which are merely overworked by defect of the remainder, are thus given the best chance of recovery. As tolerance for carbohydrates returns the dose of insulin can be reduced. I have evidence to show that in certain acute cases, obtained at an early stage, tolerance may recover to such an extent that insulin can be dispensed with. On the other hand, the damage may be so complete and so extensive that, in order to maintain health, a certain minimum of insulin must be given, as far as we know, indefinitely. Its use in diabetic coma will be considered separately. *Insulin may be employed quite safely in general practice* provided that: (*a*) One proceeds carefully and gradually in the matter of dosage, especially after the disappearance of sugar from the urine; (*b*) the patient be taught thoroughly the symptoms of overdosage, and that he or she always have at hand the means of counteracting the condition.

It must be emphasised that an overdose may result in death. Generally speaking, diabetics are more sensitive to the action of insulin than normal people, and some diabetics are much more sensitive than others. It is for these reasons that care must be taken in administering the remedy.

Symptoms Produced by an Overdose of Insulin.—The sensitiveness of patients to insulin varies—some require only a small dose to produce a certain effect, while others require a relatively large one. The effects produced are associated with a lowering of the blood-sugar, and the extent to which this takes place before symptoms arise also varies. In the majority of persons, when the blood-sugar is lowered to the region of 0·05 per cent., the symptoms of what has been termed hypoglycæmia arise. In a few patients a decrease to 0·08 per cent. only may cause the condition, whereas in others, equally few, a percentage as low as 0·04, or even 0·03, may be necessary.

The most frequent symptoms are as follows: A feeling of uneasiness, fear, a sense of impending disaster, marked physical weakness, trembling, flushing of the face and sweating, sometimes followed by pallor—the latter especially in children, in whom also the pulse-rate is often increased. Diplopia, giddiness, numbness of the hands, face, and tongue, a feeling of constriction about the chest and throat, and hunger pain may also occur. In cases of greater severity there may be ataxic movements, incoherent speech, drowsiness, and, perhaps, a state of unconsciousness; even death may ensue. The unconscious state is alarming. As a rule it resembles deep sleep in which the breathing, pulse, and appearance are good and yet the patient cannot be roused. The milder symptoms generally herald its onset, but sometimes there is no warning.

Apropos of the concentration of blood-sugar at which hypoglycæmic symptoms appear, an interesting and rather singular experience which I had with one of my earlier cases on insulin treatment may be mentioned:—

> A man, aged 60 years, moderately well nourished, had been dieted for a number of years, and during this time had remained practically free from symptoms, but always had a certain amount of sugar in the urine. When I first examined him the urine contained 5 per cent. of sugar and a small amount of diacetic acid; the blood-sugar during the morning fast was 0·303 per cent. He was given 15 units of insulin 20 minutes before a breakfast containing 7 g. C., 15 g. P., and 12 g. F. Just as the blood was about to be tested three hours after the meal he noticed for the first time that his voice had become rather thick, and a few minutes later experienced considerable difficulty in forming his words, felt chilly, unsteady on his legs, and decidedly nervous; the blood-sugar at this period showed in two simultaneous samples a percentage of 0·15. About 10 g. of glucose were given immediately by the mouth. In 15 minutes he was all right again, the blood-sugar then being 0·188 per cent.

The probable explanation of this phenomenon is that the patient's system had, in the course of years, gradually adjusted itself to the high concentration of sugar in the blood, working at this level, in much the same way as the normal does at the level of 0·1 per cent. It is therefore not altogether surprising that a sudden lowering of this concentration should have produced the symptoms described. Subsequently the blood-sugar was lowered by easy stages to normal figures, not only without recurrence of the ill-effects, but with benefit to the patient. Accordingly in chronic cases one should guard against too rapid a fall of the blood-sugar.

Treatment of Hypoglycæmia.—Nothing more than the mildest symptoms will ever occur if the simple rules for insulin therapy described later be followed.

These mild symptoms usually disappear rapidly after giving a hot drink, or a portion of the food belonging to the next meal. The patient should not be encouraged to have immediate recourse to sugar on such slight provocation. It is most important, however, that sugar be always at hand in case of emergency. If the above measures do not suffice, or if the symptoms be more marked from the start, then ½–2 oz. glucose or cane sugar must be given at once by the mouth. Recovery takes place within 10–15 minutes. Should unconsciousness have supervened, or the patient be unable to swallow, ¼–1 c.cm. of 1 in 1000 adrenalin, or ¾–1 c.cm. pituitrin, injected hypodermically, will practically always bring the patient round sufficiently within five minutes to take sugar by the mouth. If these remedies are not available, or if they do not prove effective, sugar must without delay be given intravenously. From 20 to 100 c.cm. of a 20 per cent. solution of glucose may be required. If the intravenous route fails the sugar should be injected into the subcutaneous tissues. Brandy and hot drinks are of value when consciousness has been restored. With ordinary care, however, mishaps of this nature do not occur.

Any patient who is having insulin and going about his work should as a precaution, always carry in his pocket about half-a-dozen lumps of sugar; this is really imperative if the dose be 20 units or over.

Correlation of the Diet and the Dose of Insulin.—Some physicians begin treatment by fasting the patient for a few days, or by fasting plus insulin before proceeding gradually to build up a suitable diet with the help of this remedy. The majority, however, employ the simpler method of putting the patient immediately on a diet calculated to supply his wants, and then endeavouring to restore normal metabolism by cautiously increasing the daily dose of insulin, which at first is a small one. Each method has its points. In the first one the blood-sugar is more rapidly controlled but a sufficient dietary is more slowly reached, in the second a full dietary is given from the beginning, but the decline of the hyperglycæmia is relatively slow. Further, as regards the latter, it cannot be considered the best practice in some cases, especially those in which debility is marked and the appetite poor, suddenly to throw upon the system the burden of a comparatively large meal that cannot be properly utilised. Personally, I favour an intermediate course, in which the patient is started on a diet containing roughly two-thirds of his calorie requirements and the dose of insulin gradually increased until satisfactory results are obtained. From this point a diet, sufficient for health, is steadily built up, care being taken meanwhile that the desired insulin effect is maintained by regulation of the dose. Circumstances and common sense, however, will decide in any particular instance whether at first a full diet or a fraction of it is the more applicable. As the procedure is essentially the same in both, the method of using the initial full diet will, for sake of simplicity, only be described.

The duration of the action of insulin depends partly on the size of the dose and partly on the severity of the disease. It may, for practical purposes, be put at four to eight, or roughly six, hours. The dose or doses should be so arranged that at least the bulk of the day's food is covered thereby; this applies particularly to the carbohydrate portion. In a case of any severity it is better to begin with two injections per diem; sometimes three may be necessary. As improvement takes place it may be possible to arrange the dietary so that most of it comes under the influence of a single dose without the return of symptoms. Continued progress may permit of further reduction of insulin, perhaps even its complete withdrawal occasionally. When two doses are to be given it is best to order two major and one or two minor meals in the 24 hours—e.g., a relatively large breakfast and lunch at, say, 9 A.M. and 2 P.M.; a moderately small tea at 5 o'clock, and a very light supper at 8 o'clock; bovril may be taken at 11.30 A.M. When patients are at work and away from home during the lunch-hour, it will probably be found more convenient to arrange the diet so that little is taken at midday, a meal equivalent to lunch being allowed at tea-time on the patient's return home. Insulin, in initial doses of 5 units, is given half an hour before the two larger meals; in severe cases bigger doses—e.g., 10 units—may be required. The patient should rest in bed at the beginning of treatment, or at least he should stay within doors. The 24-hour urine should be tested daily for sugar and diacetic acid. If all goes well the insulin may be increased, say, at the rate of 5 units daily, or only every second, third, or fourth day, first of all adding to the dose before lunch and then to the one before breakfast. The immediate object in view is to cause a gradual disappearance of sugar from the urine. Any single dose ought not to exceed 30 units. The effect of insulin in controlling hyperglycæmia is enhanced by reducing the carbohydrate intake and vice versa. When only one dose is indicated I find it is best to order a very light breakfast, a lunch containing almost half of the food for the 24 hours, a tea three and a half hours later, containing about one-third of the diet, and a light supper four hours afterwards; the injection is given before lunch. If insulin be discontinued, the three or four meals should be made nearly equal in food value and the interval longer than usual.

If glycosuria has been so reduced that only a small amount of sugar remains, it is valuable in the absence of blood-sugar estimations, and especially when large doses of insulin are being used, to test for sugar in the urine collected over the two hours preceding each injection. A sugar-free specimen should be an indication to proceed more carefully; it may even be advisable slightly to reduce the dosage if this be large. A 24-hour specimen free from sugar means that much has been accomplished for the patient, and the practitioner may be content to adjust the dose of insulin so that the condition just borders on glycosuria. If, however, he would secure the best results he must try to reduce the blood-sugar to a normal level. This may be effected safely by continuing the dose which had gradually freed the urine of sugar, strict watch being kept for the initial symptoms of hypoglycæmia. If none of these present themselves within four to five days, then the dose should be increased by a few units, say, every third or fourth day, until such symptoms just begin to appear. There is no danger in this procedure if the patient has been taught how to recognise and deal with the condition. The optimum dose is a little less than that which caused the symptoms. The latter may reappear as tolerance for carbohydrate improves; if so, more insulin is withdrawn.

It is, therefore, possible to treat diabetes quite satisfactorily without blood-sugar estimations, and by proceeding on these lines even the busiest practitioner can readily employ insulin with every prospect of success. The blood-tests, however, permit of a more rapid and more accurate adjustment of dosage, and consequently of an earlier and more effective rest for the pancreas. For this purpose estimations are best carried out before the first meal of the day, and three to hour hours after the injections.

The following is a brief example of the early part of the treatment advocated above:—

Patient, aged 30 years, weight 120 lb., under-nourished, urinary sugar 4 per cent., moderate degree of ketonuria, "fasting" blood-sugar in the morning 0·25 per cent., blood-sugar two hours after 20 g. glucose 0·35 per cent.

Caloric requirement (resting or at light work) = 120 × 13 = 1560 calories. A little in excess of this is ordered because the patient appears to be under-nourished. The diet as shown in Table IV. was therefore allowed.

Five units of insulin were given before breakfast and before lunch and the dose gradually increased, as described, until glycosuria was abolished and the sugar-content of the blood lowered to within normal

the patient, but calculations, &c., make it laborious for the doctor.

I have adopted a scheme of dieting which, used in conjunction with the foregoing table of "food values," has proved of great help in treating patients, both in and out of hospital. (Table II.) Menus of a number of so-called "basal" breakfasts (B_1, B_2, B_3, &c.), lunches (L_1, L_2, &c.), teas (T_1, &c.), and suppers (S_1, &c.) have been drawn up; these contain varying quantities of carbohydrate, protein, and fat. (See "System of Diets.") A dietary consisting of B_1, L_1, T_1, S_1 constitutes a 24-hour fast; for convenience the fasting diet may be referred to as D_1. Similarly, one may speak of D_2, D_3, D_4, &c.; the latter, however, are not intended to be regarded as whole-day diets, though *some* may be used as such. Of the basal breakfasts, lunches, &c., any number may be employed. Personally, I make use of 14 sets, but owing to lack of space only ten are shown. The latter will probably suffice, however, in most cases—at any rate, they serve to illustrate the principle of the method. Now the number of different 24-hour diets (consisting of B, L, T, S) that can be selected from these sets $=10^4=10{,}000$. A certain proportion of these would never be used, but taking into account the varied distribution of the diet with insulin therapy as described later, and the fact that lunches and suppers are interchangeable, also in some instances the breakfast and teas, I should think that 50 per cent. of them are capable of finding an application at some time or other.

The following is an example of a prescription: B_6, L_8, T_4, S_7. In the formula B_6, L_8, T_4, L_6, the L_6 is being used as a supper. Additional amounts of carbohydrates, protein, and fat may be added to these *basal* meals without involving more than a momentary calculation. For out-patient work or in general practice it is convenient to have the various meals printed on separate slips of paper—the patient is simply handed the requisite B, L, T, S slips and a printed list of the groups of foodstuffs, while the formula, with its values, is recorded in the notes of the case (Table III.).

TABLE III.

—	C.	P.	F.	Calories.
B_6 .. =	10·4	20·6	24·0	= 340·0
L_8 .. =	12·9	36·5	70·5	= 832·1
T_4 .. =	2·9	11·1	6·5	= 114·5
S_7 .. =	8·5	28·5	25·5	= 377·5
Total =	34·7	96·7	126·5	= 1664·1

Insulin Treatment.

We now come to the class of case—Class A, previously described—in which insulin is of outstanding value. In such, insulin treatment should be commenced without delay, especially in A (1), A (3), and A (4). The insulin, given hypodermically, compensates for the deficiency of pancreatic hormone, and in this way the metabolism of carbohydrate and fat is, more or less, restored to normal. As already stated, the aim of treatment should be to rest the islet cells as much as possible by keeping the blood-sugar concentration at, or near, the fasting level, and simultaneously to provide nourishment sufficient for the needs of the body. Those cells which are not irreparably damaged, or those which are merely overworked by defect of the remainder, are thus given the best chance of recovery. As tolerance for carbohydrates returns the dose of insulin can be reduced. I have evidence to show that in certain acute cases, obtained at an early stage, tolerance may recover to such an extent that insulin can be dispensed with. On the other hand, the damage may be so complete and so extensive that, in order to maintain health, a certain minimum of insulin must be given, as far as we know, indefinitely. Its use in diabetic coma will be considered separately. *Insulin may be employed quite safely in general practice* provided that: (*a*) One proceeds carefully and gradually in the matter of dosage, especially after the disappearance of sugar from the urine; (*b*) the patient be taught thoroughly the symptoms of overdosage, and that he or she always have at hand the means of counteracting the condition.

It must be emphasised that an overdose may result in death. Generally speaking, diabetics are more sensitive to the action of insulin than normal people, and some diabetics are much more sensitive than others. It is for these reasons that care must be taken in administering the remedy.

Symptoms Produced by an Overdose of Insulin.—The sensitiveness of patients to insulin varies—some require only a small dose to produce a certain effect, while others require a relatively large one. The effects produced are associated with a lowering of the blood-sugar, and the extent to which this takes place before symptoms arise also varies. In the majority of persons, when the blood-sugar is lowered to the region of 0·05 per cent., the symptoms of what has been termed hypoglycæmia arise. In a few patients a decrease to 0·08 per cent. only may cause the condition, whereas in others, equally few, a percentage as low as 0·04, or even 0·03, may be necessary.

The most frequent symptoms are as follows: A feeling of uneasiness, fear, a sense of impending disaster, marked physical weakness, trembling, flushing of the face and sweating, sometimes followed by pallor—the latter especially in children, in whom also the pulse-rate is often increased. Diplopia, giddiness, numbness of the hands, face, and tongue, a feeling of constriction about the chest and throat, and hunger pain may also occur. In cases of greater severity there may be ataxic movements, incoherent speech, drowsiness, and, perhaps, a state of unconsciousness; even death may ensue. The unconscious state is alarming. As a rule it resembles deep sleep in which the breathing, pulse, and appearance are good and yet the patient cannot be roused. The milder symptoms generally herald its onset, but sometimes there is no warning.

Apropos of the concentration of blood-sugar at which hypoglycæmic symptoms appear, an interesting and rather singular experience which I had with one of my earlier cases on insulin treatment may be mentioned:—

A man, aged 60 years, moderately well nourished, had been dieted for a number of years, and during this time had remained practically free from symptoms, but always had a certain amount of sugar in the urine. When I first examined him the urine contained 5 per cent. of sugar and a small amount of diacetic acid; the blood-sugar during the morning fast was 0·303 per cent. He was given 15 units of insulin 20 minutes before a breakfast containing 7 g. C., 15 g. P., and 12 g. F. Just as the blood was about to be tested three hours after the meal he noticed for the first time that his voice had become rather thick, and a few minutes later experienced considerable difficulty in forming his words, felt chilly, unsteady on his legs, and decidedly nervous; the blood-sugar at this period showed in two simultaneous samples a percentage of 0·15. About 10 g. of glucose were given immediately by the mouth. In 15 minutes he was all right again, the blood-sugar then being 0·188 per cent.

The probable explanation of this phenomenon is that the patient's system had, in the course of years, gradually adjusted itself to the high concentration of sugar in the blood, working at this level, in much the same way as the normal does at the level of 0·1 per cent. It is therefore not altogether surprising that a sudden lowering of this concentration should have produced the symptoms described. Subsequently the blood-sugar was lowered by easy stages to normal figures, not only without recurrence of the ill-effects, but with benefit to the patient. Accordingly in chronic cases one should guard against too rapid a fall of the blood-sugar.

Treatment of Hypoglycæmia.—Nothing more than the mildest symptoms will ever occur if the simple rules for insulin therapy described later be followed.

These mild symptoms usually disappear rapidly after giving a hot drink, or a portion of the food belonging to the next meal. The patient should not be encouraged to have immediate recourse to sugar on such slight provocation. It is most important, however, that sugar be always at hand in case of emergency. If the above measures do not suffice, or if the symptoms be more marked from the start, then ½–2 oz. glucose or cane sugar must be given at once by the mouth. Recovery takes place within 10–15 minutes. Should unconsciousness have supervened, or the patient be unable to swallow, ¾–1 c.cm. of 1 in 1000 adrenalin, or ¼–1 c.cm. pituitrin, injected hypodermically, will practically always bring the patient round sufficiently within five minutes to take sugar by the mouth. If these remedies are not available, or if they do not prove effective, sugar must without delay be given intravenously. From 20 to 100 c.cm. of a 20 per cent. solution of glucose may be required. If the intravenous route fails the sugar should be injected into the subcutaneous tissues. Brandy and hot drinks are of value when consciousness has been restored. With ordinary care, however, mishaps of this nature do not occur.

Any patient who is having insulin and going about his work should as a precaution, always carry in his pocket about half-a-dozen lumps of sugar; this is really imperative if the dose be 20 units or over.

Correlation of the Diet and the Dose of Insulin.—Some physicians begin treatment by fasting the patient for a few days, or by fasting plus insulin before proceeding gradually to build up a suitable diet with the help of this remedy. The majority, however, employ the simpler method of putting the patient immediately on a diet calculated to supply his wants, and then endeavouring to restore normal metabolism by cautiously increasing the daily dose of insulin, which at first is a small one. Each method has its points. In the first one the blood-sugar is more rapidly controlled but a sufficient dietary is more slowly reached, in the second a full dietary is given from the beginning, but the decline of the hyperglycæmia is relatively slow. Further, as regards the latter, it cannot be considered the best practice in some cases, especially those in which debility is marked and the appetite poor, suddenly to throw upon the system the burden of a comparatively large meal that cannot be properly utilised. Personally, I favour an intermediate course, in which the patient is started on a diet containing roughly two-thirds of his calorie requirements and the dose of insulin gradually increased until satisfactory results are obtained. From this point a diet, sufficient for health, is steadily built up, care being taken meanwhile that the desired insulin effect is maintained by regulation of the dose. Circumstances and common sense, however, will decide in any particular instance whether at first a full diet or a fraction of it is the more applicable. As the procedure is essentially the same in both, the method of using the initial full diet will, for sake of simplicity, only be described.

The duration of the action of insulin depends partly on the size of the dose and partly on the severity of the disease. It may, for practical purposes, be put at four to eight, or roughly six, hours. The dose or doses should be so arranged that at least the bulk of the day's food is covered thereby; this applies particularly to the carbohydrate portion. In a case of any severity it is better to begin with two injections per diem; sometimes three may be necessary. As improvement takes place it may be possible to arrange the dietary so that most of it comes under the influence of a single dose without the return of symptoms. Continued progress may permit of further reduction of insulin, perhaps even its complete withdrawal occasionally. When two doses are to be given it is best to order two major and one or two minor meals in the 24 hours—e.g., a relatively large breakfast and lunch at, say, 9 A.M. and 2 P.M.; a moderately small tea at 5 o'clock, and a very light supper at 8 o'clock; bovril may be taken at 11.30 A.M. When patients are at work and away from home during the lunch-hour, it will probably be found more convenient to arrange the diet so that little is taken at midday, a meal equivalent to lunch being allowed at tea-time on the patient's return home. Insulin, in initial doses of 5 units, is given half an hour before the two larger meals; in severe cases bigger doses—e.g., 10 units—may be required. The patient should rest in bed at the beginning of treatment, or at least he should stay within doors. The 24-hour urine should be tested daily for sugar and diacetic acid. If all goes well the insulin may be increased, say, at the rate of 5 units daily, or only every second, third, or fourth day, first of all adding to the dose before lunch and then to the one before breakfast. The immediate object in view is to cause a gradual disappearance of sugar from the urine. Any single dose ought not to exceed 30 units. The effect of insulin in controlling hyperglycæmia is enhanced by reducing the carbohydrate intake and vice versa. When only one dose is indicated I find it is best to order a very light breakfast, a lunch containing almost half of the food for the 24 hours, a tea three and a half hours later, containing about one-third of the diet, and a light supper four hours afterwards; the injection is given before lunch. If insulin be discontinued, the three or four meals should be made nearly equal in food value and the interval longer than usual.

If glycosuria has been so reduced that only a small amount of sugar remains, it is valuable in the absence of blood-sugar estimations, and especially when large doses of insulin are being used, to test for sugar in the urine collected over the two hours preceding each injection. A sugar-free specimen should be an indication to proceed more carefully; it may even be advisable slightly to reduce the dosage if this be large. A 24-hour specimen free from sugar means that much has been accomplished for the patient, and the practitioner may be content to adjust the dose of insulin so that the condition just borders on glycosuria. If, however, he would secure the best results he must try to reduce the blood-sugar to a normal level. This may be effected safely by continuing the dose which had gradually freed the urine of sugar, strict watch being kept for the initial symptoms of hypoglycæmia. If none of these present themselves within four to five days, then the dose should be increased by a few units, say, every third or fourth day, until such symptoms just begin to appear. There is no danger in this procedure if the patient has been taught how to recognise and deal with the condition. The optimum dose is a little less than that which caused the symptoms. The latter may reappear as tolerance for carbohydrate improves; if so, more insulin is withdrawn.

It is, therefore, possible to treat diabetes quite satisfactorily without blood-sugar estimations, and by proceeding on these lines even the busiest practitioner can readily employ insulin with every prospect of success. The blood-tests, however, permit of a more rapid and more accurate adjustment of dosage, and consequently of an earlier and more effective rest for the pancreas. For this purpose estimations are best carried out before the first meal of the day, and three to hour hours after the injections.

The following is a brief example of the early part of the treatment advocated above:—

Patient, aged 30 years, weight 120 lb., under-nourished, urinary sugar 4 per cent., moderate degree of ketonuria. "fasting" blood-sugar in the morning 0·25 per cent., blood-sugar two hours after 20 g. glucose 0·35 per cent.

Calorie requirement (resting or at light work)= 120 × 13= 1560 calories. A little in excess of this is ordered because the patient appears to be under-nourished. The diet as shown in Table IV. was therefore allowed.

Five units of insulin were given before breakfast and before lunch and the dose gradually increased, as described, until glycosuria was abolished and the sugar-content of the blood lowered to within normal

limits. This result was attained when 10 units were being given before breakfast and 15 before lunch. Later, by rearrangement of the diet, one was enabled to reduce the number of injections to once daily (Table V.).

TABLE IV.

—	C.	P.	F.	Calories.
B_7 .. =	10·2	22·6	32·0	= 419·2
L_8 .. =	12·9	36·5	70·5	= 832·1
T_7 .. =	7·6	19·7	27·5	= 356·7
S_2 .. =	2·0	5·6	0·5	= 34·9
Total =	32·7	84·4	130·5	= 1642·9

TABLE V.

—	C.	P.	F.	Calories.
B_3 .. .. .. =	2·0	10·6	1·5	= 63·9
L_8 + ½ oz. bread .. =	19·5	37·7	70·5	= 863·3
T_8 .. .. .. =	8·3	18·2	40·0	= 466·0
S_3 + ½ oz. butter .. =	1·2	11·3	17·0	= 203·0
Total .. .. =	31·0	77·8	129·0	=1596·2

Insulin, 20 units, given before lunch controls both lunch and tea; breakfast and supper throw but little stress on the pancreas. It is hardly necessary to illustrate the method further. In instances when the patient is only able to afford a fraction of the required dose, or when the supply is restricted, it is better to give this amount than none at all; metabolism is thereby brought nearer to the normal.

Treatment of Diabetic Coma with Insulin.

The presence of sugar and diacetic acid in the urine in a case of coma is sufficient indication for the immediate use of insulin. An initial dose of 25 to 35 units should be given, and repeated in one and a half to two hours if there is not appreciable improvement. When possible, blood-sugar estimations ought to be made at intervals in order to observe the effect of insulin. On the one hand, it may be that enough is not being given, on the other, it is possible that the dose may prove so great that the coma passes imperceptibly into the unconscious stage of marked hypoglycæmia. Blood examinations are clearly of great value in conditions of this sort. Should their aid not be available, the question of giving sugar in order to guard against hypoglycæmia has to be carefully considered. In most cases the action of insulin is dramatic, the patient making a rapid and remarkable recovery. Even after consciousness has been regained close observation is essential, and a supply of adrenalin and sugar ought to be always at hand in case of emergency.

Instruction of the Patient.

The patient's future depends greatly on his intelligence and on his faithfulness to treatment. To gain his coöperation, he should be instructed in points such as the following:—

(*a*) *The nature of his disease.*

(*b*) The principle that treatment depends on diet and not on drugs.

(*c*) The meaning of carbohydrate, protein, and fat, and how each of these foodstuffs affects the disease.

(*d*) How to measure out diets. [He ought to provide himself with scales weighing to 10 oz., and a 10-oz. fluid measure. After a little experience the amounts may be gauged accurately enough without their use.]

(*e*) The method of rendering the urine *sugar-free.*

(*f*) The care of the teeth and skin.

(*g*) The testing of a specimen of the 24 hours' urine for sugar. This should be done daily or every other day. The following is a very simple method: Half fill a tablespoon (if test-tube not available) with Benedict's solution and add 10 drops of urine. Boil for two minutes; if no reduction during this process, set aside to cool for 3–4 minutes: a clear solution then means absence of sugar.

It may be necessary to teach the patient how to inject himself with insulin. Patients having insulin should know the symptoms of hypoglycæmia and how to act when they appear. If the blood-sugar is being kept at a low level by large doses, sleep should not be allowed within six hours following an injection. If the supply of insulin fails, the diet should be reduced by half; subsequently it may be raised to two-thirds.

3. PROGNOSIS.

No definite prognosis should be given until the patient's response to treatment has been thoroughly tested. This, taken in conjunction with the history of the case and the general condition of the patient, is the best guide to the severity of the disease or the degree of permanent damage. The significance of factors such as age, habit of body, duration of the disease, state of nutrition, and the amount of weight lost is well known, and will be taken into account.

Insulin has so revolutionised the treatment of cases both mild and severe, early and chronic, that we must allow the lapse of time before making any comprehensive statement on prognosis. As far as my experience goes, very early cases, with a clearly-defined onset, do remarkably well on insulin treatment, rigorously applied from the commencement. For example, in September last I treated a man, aged 20 years, who gave a history of the sudden onset of marked thirst, polyuria, and general weakness, beginning a week previously. The weight was normal and no infection could be found. Three per cent. sugar and much diacetic acid were found in the urine. The fasting blood-sugar was 0·176 per cent.; three-quarters of an hour after a small carbohydrate meal the percentage was 0·297, and at the two-hour period 0·261. After four days' insulin (10 units b.d.) and dietetic treatment the blood-sugar was normal. No reduction in the dose was made until five days later. During the course of the following three weeks the remedy was gradually, and at last completely, withdrawn. Since then, examinations at weekly intervals have not detected any sign of relapse. The daily allowance of carbohydrate is, however, still restricted, being only 65 g. Whether the patient would have developed the disease in any severity without insulin, or whether dietetic measures alone would have sufficed cannot be decided. The degree of liability to a recurrence of the trouble is also unknown.

Looked at from the standpoint of restoration of tolerance alone insulin greatly enhances the prospects for the patient by ensuring that the pancreas has a better chance of recovery than with purely dietetic measures. As regards ultimate results it is too early to speak. So far, experience suggests that a patient may be kept going indefinitely on insulin. In only three out of a series of 31 cases of mine treated for periods ranging from three to seven months has the disease appeared to be progressive once the blood-sugar has been properly controlled; one of the three was afflicted by a marked chronic nasal catarrh, which fact may partly explain the disappointing result.

The question which arises with the majority of patients, however, is whether or not the remedy may be partially or totally withdrawn after a time without a relapse. It is only by prolonged observation of the response to treatment that an answer can be arrived at. For some the problem resolves itself, more or less, into one of constant supply, while for others there is the encouragement of good results already obtained and the hope that, at most, only a small or occasional dose of insulin may eventually be required to protect the functioning islet tissue against extension or renewal of the disease.

Summary.

Special attention has been directed to: (*a*) The feasibility of diagnosing and treating diabetes mellitus without blood-sugar estimations. The value of the latter has been indicated. (*b*) The simplification of dietetic treatment.

In conclusion, I wish to express my sincere thanks to Prof. F. Langmead for much valuable advice, and for his kindness in allowing me to make use of his cases.

Clinical and Laboratory Notes.

HEPATIC ABSCESS AS A COMPLICATION OF APPENDICITIS.

BY E. G. SLESINGER, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, GUY'S HOSPITAL.

THE case reported below is unusual in that after discharge of an appendicular abscess by the rectum for two years, hepatic abscess occurred, and in that although multiple infarction of the lung followed operation, a perfect recovery ultimately ensued.

H. B., male, aged 45, was first seen with Dr. T. Bowes, of Herne Bay, on June 26th, 1922.

History.—The history then obtained was as follows. Two years previously he had had an attack of acute intestinal obstruction, for which he was operated on, a mass of uncertain nature being found in the right iliac fossa. A lateral anastomosis of the terminal ileum to the ascending colon was performed. This partly relieved the obstruction, and shortly after an abscess burst into the rectum. Since that time, at varying intervals of from two weeks to two months, he had had attacks of pyrexia, abdominal pain, and pain on micturition, which lasted for a short time and were followed by the discharge of pus per rectum with relief, a state of affairs which had kept him more or less an invalid for two years. For the past two weeks he had been feeling very ill, with pyrexia and pain in the left epigastric region. This was quite different from the usual type of pain preceding the discharge of pus from the rectum. There was no history of dysentery and several examinations of the stools had proved negative.

Condition on Examination.—The patient looked ill and had marked clubbing of the fingers. There was dullness with greatly diminished breath sounds at the left base, rigidity of the upper part of the left rectus, dullness and a well-marked "cracked-pot" note over the front of the lower left ribs, and the liver felt slightly enlarged or pushed down. On rectal examination a large mass could be felt in Douglas's pouch. A provisional diagnosis of left subphrenic abscess was made.

Operation.—The next day, under an anæsthetic, the left base was needled in several places, but no pus or fluid was found. A high left paramedian incision was made and the subphrenic region was explored, but with negative result. The left lobe of the liver was seen to be congested and a needle was pushed in, pus being found at once. An incision into the liver opened an abscess cavity the size of a large egg-cup, filled with white odourless pus. This was drained with a large tube. The pus showed neither amœbæ nor actinomyces and remained sterile on culture. Bile discharged from the wound on the tenth day. Convalescence was very prolonged and was interrupted by repeated attacks of pulmonary infarction of the right lung, with spitting of first blood and later pus, and with high temperature and rigors. Gradually the condition improved, and the wound was fully healed [illegible] four months. Some cough and the usual abdominal [illegible] with discharge of pus from the rectum continued.

On Dec. 21st, 1922, he was again admitted with [illegible] clearing up the abdominal condition. X ray [illegible] showed the ileo-colostomy to be working well and [illegible] of the chest showed little except some darkening [illegible] side. On sigmoidoscopy marked œdema [illegible] mucosa, especially on the right side, was [illegible] actual sinus could be demonstrated. Dr. [illegible] examined the patient, found signs of [illegible] in the right lung. In spite of the [illegible] examinations of the stools, emetine [illegible] for ten days but with no effect.

On Jan. 4th, 1923, the abdomen [illegible] right paramedian incision. The [illegible] normal. A thick, rigid appendix [illegible] pelvic wall, was found and [illegible] Convalescence was rapid, and [illegible] his normal weight. [illegible] abdominal or chest symptoms [illegible] carrying on his duties [illegible] health.

Stillman, in a [illegible] found that comp[illegible] of these only [illegible] series of 2714 [illegible] various [illegible] occurred [illegible] reported [illegible]

only find 14 cases of liver abscess treated, with 12 recoveries, and they note that three of these were probably subphrenic. They record seven other cases. Since that date Bittner, Brogden, Le Petit, Frank, and Kelly have each had a recovery from this condition, so that records exist of 23 cases, of which 20 are known to have recovered after operative treatment. Many other cases, of course, were only recognised to have a solitary liver abscess on post-mortem examination.

It is of interest to note that the left lobe was very frequently the seat of the abscess in contra-distinction to the far greater frequency of right lobe infection in other solitary abscesses. The surprisingly high recovery-rate in these cases is, no doubt, partly due to the fact that only the patients with a relatively mild infection develop a solitary abscess, but in this connexion the work of Lemaire is also of interest. His experiments show that to a certain extent the liver offers a protection against a general infection with the *Bacillus coli communis*, and indicate that this office is performed by the endothelial cells of the hepatic capsule, purification taking place in a few hours if the infection is not too severe. This fact probably accounts for the sterility of the pus found at operation in my case and in several of the others.

AN UNUSUAL CASE OF PRIMARY CARCINOMA OF LIVER.

BY E. W. JOHNSON, L.R.C.P., [illegible]
SMITHDOWN-ROAD [illegible]

CARCINOMA of the liver is [illegible] primary. It is a disease [illegible] half the cases occurring [illegible] sixtieth years (Leich[illegible]). [illegible] occasionally occurs in children. [illegible] three varieties are [illegible] nodular, in which [illegible] throughout the [illegible] solitary [illegible] so-called [illegible] belongs [illegible] to be sufficient [illegible]

[illegible] with the following [illegible]

[illegible] at the age of [illegible] of the finger [illegible] for admission [illegible] [illegible] finding long [illegible] [illegible] contracted [illegible] operation [illegible] from the [illegible] with a hollow [illegible] was [illegible] closed. [illegible]

[illegible] in addition to [illegible] of the liver [illegible]

limits. This result was attained when 10 units were being given before breakfast and 15 before lunch. Later, by rearrangement of the diet, one was enabled to reduce the number of injections to once daily (Table V.).

TABLE IV.

—	C.	P.	F.	Calories.
B_7 .. =	10·2	22·6	32·0	= 419·2
L_8 .. =	12·9	36·5	70·5	= 832·1
T_7 .. =	7·6	19·7	27·5	= 356·7
S_2 .. =	2·0	5·6	0·5	= 34·9
Total =	32·7	84·4	130·5	= 1642·9

TABLE V.

—	C.	P.	F.	Calories.
B_3 .. .. .. =	2·0	10·6	1·5	= 63·9
L_9 + ½ oz. bread .. =	19·5	37·7	70·5	= 863·3
T_8 .. .. .. =	8·3	18·2	40·0	= 466·0
S_3 + ½ oz. butter .. =	1·2	11·3	17·0	= 203·0
Total .. .. =	31·0	77·8	129·0	=1596·2

Insulin, 20 units, given before lunch controls both lunch and tea; breakfast and supper throw but little stress on the pancreas. It is hardly necessary to illustrate the method further. In instances when the patient is only able to afford a fraction of the required dose, or when the supply is restricted, it is better to give this amount than none at all; metabolism is thereby brought nearer to the normal.

Treatment of Diabetic Coma with Insulin.

The presence of sugar and diacetic acid in the urine in a case of coma is sufficient indication for the immediate use of insulin. An initial dose of 25 to 35 units should be given, and repeated in one and a half to two hours if there is not appreciable improvement. When possible, blood-sugar estimations ought to be made at intervals in order to observe the effect of insulin. On the one hand, it may be that enough is not being given, on the other, it is possible that the dose may prove so great that the coma passes imperceptibly into the unconscious stage of marked hypoglycæmia. Blood examinations are clearly of great value in conditions of this sort. Should their aid not be available, the question of giving sugar in order to guard against hypoglycæmia has to be carefully considered. In most cases the action of insulin is dramatic, the patient making a rapid and remarkable recovery. Even after consciousness has been regained close observation is essential, and a supply of adrenalin and sugar ought to be always at hand in case of emergency.

Instruction of the Patient.

The patient's future depends greatly on his intelligence and on his faithfulness to treatment. To gain his coöperation, he should be instructed in points such as the following:—

(*a*) The nature of his disease.

(*b*) The principle that treatment depends on diet and not on drugs.

(*c*) The meaning of carbohydrate, protein, and fat, and how each of these foodstuffs affects the disease.

(*d*) How to measure out diets. [He ought to provide himself with scales weighing to 10 oz., and a 10-oz. fluid measure. After a little experience the amounts may be gauged accurately enough without their use.]

(*e*) The method of rendering the urine sugar-free.

(*f*) The care of the teeth and skin.

(*g*) The testing of a specimen of the 24 hours' urine for sugar. This should be done daily or every other day. The following is a very simple method: Half fill a tablespoon (if test-tube not available) with Benedict's solution and add 10 drops of urine. *Boil for two minutes*; if no reduction during this process, set aside to cool for 3–4 minutes: a clear solution then means absence of sugar.

It may be necessary to teach the patient how to inject himself with insulin. Patients having insulin should know the symptoms of hypoglycæmia and how to act when they appear. If the blood-sugar is being kept at a low level by large doses, sleep should not be allowed within six hours following an injection. If the supply of insulin fails, the diet should be reduced by half; subsequently it may be raised to two-thirds.

3. PROGNOSIS.

No definite prognosis should be given until the patient's response to treatment has been thoroughly tested. This, taken in conjunction with the history of the case and the general condition of the patient, is the best guide to the severity of the disease or the degree of permanent damage. The significance of factors such as age, habit of body, duration of the disease, state of nutrition, and the amount of weight lost is well known, and will be taken into account.

Insulin has so revolutionised the treatment of cases both mild and severe, early and chronic, that we must allow the lapse of time before making any comprehensive statement on prognosis. As far as my experience goes, very early cases, with a clearly-defined onset, do remarkably well on insulin treatment, rigorously applied from the commencement. For example, in September last I treated a man, aged 20 years, who gave a history of the sudden onset of marked thirst, polyuria, and general weakness, beginning a week previously. The weight was normal and no infection could be found. Three per cent. sugar and much diacetic acid were found in the urine. The fasting blood-sugar was 0·176 per cent.; three-quarters of an hour after a small carbohydrate meal the percentage was 0·297, and at the two-hour period 0·261. After four days' insulin (10 units b.d.) and dietetic treatment the blood-sugar was normal. No reduction in the dose was made until five days later. During the course of the following three weeks the remedy was gradually, and at last completely, withdrawn. Since then, examinations at weekly intervals have not detected any sign of relapse. The daily allowance of carbohydrate is, however, still restricted, being only 65 g. Whether the patient would have developed the disease in any severity without insulin, or whether dietetic measures alone would have sufficed cannot be decided. The degree of liability to a recurrence of the trouble is also unknown.

Looked at from the standpoint of restoration of tolerance alone insulin greatly enhances the prospects for the patient by ensuring that the pancreas has a better chance of recovery than with purely dietetic measures. As regards ultimate results it is too early to speak. So far, experience suggests that a patient may be kept going indefinitely on insulin. In only three out of a series of 31 cases of mine treated for periods ranging from three to seven months has the disease appeared to be progressive once the blood-sugar has been properly controlled; one of the three was afflicted by a marked chronic nasal catarrh, which fact may partly explain the disappointing result.

The question which arises with the majority of patients, however, is whether or not the remedy may be partially or totally withdrawn after a time without a relapse. It is only by prolonged observation of the response to treatment that an answer can be arrived at. For some the problem resolves itself, more or less, into one of constant supply, while for others there is the encouragement of good results already obtained and the hope that, at most, only a small or occasional dose of insulin may eventually be required to protect the functioning islet tissue against extension or renewal of the disease.

Summary.

Special attention has been directed to: (*a*) The feasibility of diagnosing and treating diabetes mellitus without blood-sugar estimations. The value of the latter has been indicated. (*b*) The simplification of dietetic treatment.

In conclusion, I wish to express my sincere thanks to Prof. F. Langmead for much valuable advice, and for his kindness in allowing me to make use of his cases.

other was applicable to both eradicable and ineradicable cancer. It had a cauterising and coagulating effect on the diseased tissues, and also an antiseptic effect by which tissues surrounding the growth were sterilised of bacteria. He described the procedure he followed in cases of varying degrees in both categories.

Anastomosis of Facial and Recurrent Laryngeal Nerves with other Nerves.

Sir **CHARLES BALLANCE** communicated a preliminary note on results he had obtained in some experiments in which the facial and recurrent laryngeal nerves were anastomosed with other nerves. The research was carried out in conjunction with Mr. L. Colledge, Dr. Lionel Bell, Sir David Ferrier, and Prof. S. G. Shattock, the last-named until he was attacked by illness; the inquiry is still in progress. After end-to-end anastomosis of the recurrent laryngeal and the vagus, there was found to be no movement on tranquil respiration, therefore the object was not attained. But at the end of 15 months, when the wound was reopened and the vagus was stimulated above the point of anastomosis, the vocal cord abducted. Still, at the end of 18 months there was no cord movement on tranquil respiration, nor on asphyxiation, showing, therefore, that a partial degeneration of function had taken place, and hence the anastomosis could not be regarded as a physiological one. A similar sequel was observed of end-to-end anastomosis of the descendens noni with the recurrent laryngeal. But the phrenic nerve seemed a likely one. Therefore, this was divided and a divided recurrent laryngeal was united to it end-to-end. It was necessary to arrange for the nerve-supply of the diaphragm, therefore the distal end of the recurrent laryngeal was united end-to-end with the cut descendens noni. To prevent atrophy of the depressor muscles of the larynx and hyoid bone, the distal end of the descendens noni was anastomosed end-to-side with the hypoglossal. These depressor muscles of the hyoid bone were now acting normally, and their electrical reactions were normal; also the diaphragm was reported to be working normally through the descendens noni. With regard to the anastomosis between recurrent laryngeal and phrenic, at the end of a few months both cords were found to be acting normally and harmoniously, and a little later the anastomosed phrenic nerve was acting a little too vigorously; hence the experiment had overdone what was aimed at, perhaps because the recurrent laryngeal energised a much bigger muscle now than under natural circumstances. A further experiment was to anastomose the recurrent laryngeal to half the phrenic, and in another the fourth root was employed. The result was that he was satisfied that the phrenic nerve would energise and produce rhythmical movement of a vocal cord corresponding to the movement of the other cord.

With regard to the facial nerve, in 1895 the first anastomosis was done for the relief of facial palsy; it was an end-to-end anastomosis of the facial with the spinal accessory. The result of this procedure was, practically always, recovery of the face after many months, but with an associated movement of the shoulder, so that when the shoulder was moved the whole side of the face twitched. The next nerve to be tried was the hypoglossal, but associated movements could not be entirely obviated. A happier result followed anastomosis between the glosso-pharyngeal and the facial. He considered, as a result of this work, that the glosso-pharyngeal was the nerve which could be used by surgeons for the recovery of motion in the face after the onset of paralysis there; also that a portion of the phrenic nerve could well be used in order to achieve recovery of movement in a paralysed condition of vocal cords.

The communication was discussed by Sir **DAVID FERRIER**, Sir **FREDERICK MOTT**, Dr. **W. S. SYME**, and Sir **W. MILLIGAN**.

A large number of clinical cases were shown and discussed.

Otological and Rhinological Problems in Scarlet Fever and Measles.

Mr. T. B. **LAYTON** initiated a discussion on this topic. One of the chief problems he mentioned was that presented by the child who, after convalescing from scarlet fever, still had a discharge from the ear. Was there a risk that such a child would infect others when he again went into the community? If so, one was faced with either having to keep the child in the fever hospital for a considerable time, or doing an operation on him. The question of the carrier in nose and ear disease was one which would have to be faced in the near future. With regard to mastoiditis in scarlet fever, most authorities considered there was no need for great anxiety concerning extension of disease from bone to the meninges. Much the same problems were presented in measles patients, but as fewer cases of this disease were taken into fever hospitals, there were fewer opportunities of studying them. Sinusitis he did not regard as very common during infectious diseases.

Dr. **KERR LOVE** said that as an aid to treatment, tonsils and adenoids should be removed as soon as it was safe to do so—i.e., after the fever had subsided. The school authorities should not readmit a child with a running ear after an attack of either scarlet fever or measles. He believed that suggestions would be adopted by the County of Dumbarton and the City of Glasgow authorities.—Sir **WILLIAM MILLIGAN** said the time to take concerted action on this most important matter to the rising generation was long overdue. These destructive processes in the ear were a great handicap. Adenoids should be removed during the disease—i.e., as soon as the temperature came down; the removal should not be deferred until the patient was convalescent.—Mr. J. **ADAM** said that of 62 cases who developed otitis media only five required mastoid operation, which seemed to show that the tendency was for otitis media to get well if no operation was done.—Dr. **MCKENZIE** thought the mastoid should be operated upon more frequently in these cases of discharging ears. The question of secondary paracentesis should never arise.—Mr. **NEIL MACLAY** said that out of the large number of cases of scarlet fever admitted to the Newcastle Fever Hospital he had never seen the large devastating perforations which were described in the text-books. It was very difficult to anticipate the discharge by paracentesis, but efforts were made to cleanse mouth, fauces, and ears. Tonsils and adenoids, if prominent, were removed at an early period. Mr. J. S. **FRASER** agreed with Dr. McKenzie as to secondary paracentesis; he had never seen a secondary paracentesis do any good. He believed that if the rhinitis resulting from scarlet fever and measles were cured, much ozæna would be obviated in the future.—The discussion was continued by Mr. **HUGH JONES**, Dr. **SYDENHAM**, Mr. **BANKS-DAVIS**, Mr. **GILLESPIE**, Dr. F. W. **HARTOG**, Dr. A. D. **SHARP**, and Mr. J. F. **O'MALLEY**, and Mr. **LAYTON** replied.

Dr. P. **WATSON-WILLIAMS** read a paper on the Clinical Importance of Nasal Sinus Infection in Mastoiditis.

Dr. **ALBERT A. GRAY** gave a demonstration of stereoscopic slides for teaching purposes. Coloured representations of minute anatomy could be seen in three dimensions by means of simple two-colour (red and green) spectacle frames worn by the observers.

SECTION OF UROLOGY.

POLYCYSTIC DISEASE OF THE KIDNEY.

A MEETING of this section was held on June 26th, Dr. **LANGDON BROWN**, the President, being in the chair, when Dr. **PARKES WEBER** read a paper on the

So-called Myelin Kidney.

He explained that his interest was originally aroused in this subject by the numerous examples of opaque specks and streaks seen in the routine work of the post-mortem room. Some of these streaks were shown to be minute adenomata, others small cysts

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF LARYNGOLOGY AND OTOLOGY: SUMMER CONGRESS.

A SUMMER Congress of these sections in association was held at 1, Wimpole-street, London, on June 26th, 27th, and 28th, under the chairmanship of the respective section presidents, Mr. H. J. **BANKS-DAVIS** and Mr. **SYDNEY SCOTT**. Among the foreign visitors were Prof. R. Magnus and Dr. De Kleijn (Utrecht) and Dr. Hartog (The Hague); a dinner was held on the 27th, and river excursions took place on Sunday the 29th, the latter on the invitation of Mr. Irwin Moore.

Miss E. **LOWRY** read a paper on

Throat and Ear Defects of the Elementary School Child.

She pleaded for a more sympathetic attitude on this matter on the part of the profession as a whole. There was still no provision for the treatment of tonsils and adenoids in the case of 89 educational authorities in this country, and at some centres there was no arrangement for treating diseased ears. In quite a number the light for examination was inadequate, and at some the practice was simply to syringe out the ear to ascertain if anything came away. The best clinics were those attached to hospitals or where the work was done by those holding hospital appointments.—Mr. J. S. **FRASER** advocated the cessation of all school procedure for a time to permit of hearing tests being carried out; the gross testing could easily be done by the teachers, the ears being separately tested, and the child's face turned away to prevent lip-reading.—Sir **JAMES DUNDAS-GRANT** did not think the tests should be too delicate, but there was need for much general attention to this question among the children.—Mr. **DOUGLAS GUTHRIE** referred to the difficulty often experienced in getting the family doctor to do anything when the defect had been pointed out to him. It would be very interesting to know what happened later to these cases, and therefore a system of following them up would yield useful information.

Various Communications.

Dr. A. **BROWN KELLY** read a paper on Tortuosity of the Internal Carotid in Relation to the Pharynx. He showed that it nearly always occurred in the lateral part of the posterior wall, and it might be either unilateral or bilateral. It might occur in young growing people, therefore was not always due to age, as had been supposed.

Dr. W. S. **SYME** spoke on Displacement of the Antro-nasal Wall in the Treatment of Atrophic Rhinitis, emphasising the need of doing all that was possible to obviate distressing ozæna. He described the operation and spoke of very satisfactory results, especially in regard to ozæna.

Mr. **IRWIN MOORE** gave a communication on Chondromata and Chondro-osteomata of the Larynx, based upon a study of 20 cases recorded and described in the literature, and indicated what he considered to be the best means to treat this condition.

Sir **STCLAIR THOMSON** read a paper on Ecchondrosis of the Larynx, recording two cases of the condition which he had treated by laryngo-fissure.

Mr. A. L. **YATES** submitted a description of the methods he had adopted for determining the activity of the ciliated epithelium in certain cases of sinusitis. He pointed out that when there was stasis of the fluid mucus in the nose it was due to paralysis of the epithelium, ciliæ being paralysed by the toxins of the organisms present.—Sir **STCLAIR THOMSON** characterised this as a most valuable piece of work, and referred to his own inquiry into the subject many years ago.

Prof. **MAGNUS** gave an address on the

Experimental Basis for Theories on Vestibular Function.

He said it was necessary to make a sharp distinction between the function of the canals and the function of the auditory apparatus, ascribing to the canals all reactions to rotations, and to the otolitic apparatus all reactions depending on certain positions and the sensations of rectilinear movements. He submitted the following schedule:—

Labyrinthine Reflexes.—1. Reflexes corresponding to movements: Rotatory reactions: (*a*) on head; (*b*) on eyes; (*c*) on limbs; (*d*) on trunk. 2. Reflexes resulting from positions: (*a*) on limbs; (*b*) on neck (and trunk). Labyrinthine righting reflexes: (*a*) Asymmetrical; (*b*) symmetrical. Compensatory eye positions: (*a*) Vertical; (*b*) rotatory.

Discussing the possibility of ascertaining which reflexes were of the canals and which of the otolithic apparatus, he said that if the guinea-pig were centrifugalised at high speed the otolithic membranes could be placed completely out of action, the canal remaining normally responsive. The experiments showed that the epithelium of the macula, without any action of or connexion with otolithic membranes, was able to produce in its own metabolism excitations, hence it must be assumed that the function of the otolithic membrane was to increase or decrease the amount of excitation produced in the metabolism of the cells. In the mucous mass of the otolithic membrane were embedded crystals of calcium carbonate, and the total weight of these crystals in a single otolith membrane was about one-fiftieth of a milligramme. Further careful experimentation showed that the utricles and the otoliths were connected with these reflexes, and that the maximal effect of the otolithic apparatus was not, as formerly supposed, produced by shifting, but by pressing or pulling on the epithelium. Concerning rotatory eye positions, it had not been possible to make out with certainty from which part of the labyrinth those reflexes arose, but experiments were still being continued in Utrecht to settle the point. For the vertical eye position, however, the results were very clear. With both labyrinths intact, in rabbit and guinea-pig, there was no vertical eye deviation; but if one labyrinth were restricted the well-known vertical eye deviation occurred, and this eye deviation was found to depend on changes of the head position in space. In the lateral position it was at zero, or certainly minimal. He proceeded to show that the findings were in accordance with the minute anatomy of the parts, and asked for evidence from practising otologists on the clinical side.

Dr. **DE KLEIJN** followed with a demonstration on the epidiascope of the compensatory eye positions in patients. He pointed out the importance of excluding the tonic reflexes of the eye muscles, which arose when the position of the head in relation to the trunk was changed; therefore the position of the head in relation to the trunk must remain fixed. Similarly, reflexes due to movements must be excluded.

Mr. A. R. **TWEEDIE** discussed the subject of vertigo in relation to otolith and neck reflexes.

Sir **WILLIAM MILLIGAN** read a paper on

Malignant Disease of the Naso-Pharynx,

which was illustrated by lantern slides. He spoke of the value of a preliminary irradiation of the growth, as it caused a marked shrinkage and lessened the risk of disconcerting hæmorrhage. He favoured the insertion of small glass tubes charged with radium emanations. Radium he had found of great value for growths in regard to which ordinary surgery was contra-indicated. He objected to the splitting of the palate, preferring to gain efficient access by doing lateral rhinotomy. Surgery offered less hope for these cases than did radium.—Mr. **SYDNEY SCOTT** deplored the fact that these cases were seen too late because physicians too often treated the symptoms instead of investigating the possible causes.

Dr. **DAN MCKENZIE**, in an exhaustive treatment of the subject of

Diathermy for Pharyngeal Cancer,

said no remedy hitherto available could equal diathermy in the treatment of cancer of the throat; no other was applicable to both eradicable and ineradicable cancer. It had a cauterising and coagulating effect on the diseased tissues, and also an antiseptic effect by which tissues surrounding the growth were sterilised of bacteria. He described the procedure he followed in cases of varying degrees in both categories.

Anastomosis of Facial and Recurrent Laryngeal Nerves with other Nerves.

Sir CHARLES BALLANCE communicated a preliminary note on results he had obtained in some experiments in which the facial and recurrent laryngeal nerves were anastomosed with other nerves. The research was carried out in conjunction with Mr. L. Colledge, Dr. Lionel Bell, Sir David Ferrier, and Prof. S. G. Shattock, the last-named until he was attacked by illness; the inquiry is still in progress. After end-to-end anastomosis of the recurrent laryngeal and the vagus, there was found to be no movement on tranquil respiration, therefore the object was not attained. But at the end of 15 months, when the wound was reopened and the vagus was stimulated above the point of anastomosis, the vocal cord abducted. Still, at the end of 18 months there was no cord movement on tranquil respiration, nor on asphyxiation, showing, therefore, that a partial degeneration of function had taken place, and hence the anastomosis could not be regarded as a physiological one. A similar sequel was observed of end-to-end anastomosis of the descendens noni with the recurrent laryngeal. But the phrenic nerve seemed a likely one. Therefore, this was divided and a divided recurrent laryngeal was united to it end-to-end. It was necessary to arrange for the nerve-supply of the diaphragm, therefore the distal end of the recurrent laryngeal was united end-to-end with the cut descendens noni. To prevent atrophy of the depressor muscles of the larynx and hyoid bone, the distal end of the descendens noni was anastomosed end-to-side with the hypoglossal. These depressor muscles of the hyoid bone were now acting normally, and their electrical reactions were normal; also the diaphragm was reported to be working normally through the descendens noni. With regard to the anastomosis between recurrent laryngeal and phrenic, at the end of a few months both cords were found to be acting normally and harmoniously, and a little later the anastomosed phrenic nerve was acting a little too vigorously; hence the experiment had overdone what was aimed at, perhaps because the recurrent laryngeal energised a much bigger muscle now than under natural circumstances. A further experiment was to anastomose the recurrent laryngeal to half the phrenic, and in another the fourth root was employed. The result was that he was satisfied that the phrenic nerve would energise and produce rhythmical movement of a vocal cord corresponding to the movement of the other cord.

With regard to the facial nerve, in 1895 the first anastomosis was done for the relief of facial palsy; it was an end-to-end anastomosis of the facial with the spinal accessory. The result of this procedure was, practically always, recovery of the face after many months, but with an associated movement of the shoulder, so that when the shoulder was moved the whole side of the face twitched. The next nerve to be tried was the hypoglossal, but associated movements could not be entirely obviated. A happier result followed anastomosis between the glosso-pharyngeal and the facial. He considered, as a result of this work, that the glosso-pharyngeal was the nerve which could be used by surgeons for the recovery of motion in the face after the onset of paralysis there; also that a portion of the phrenic nerve could well be used in order to achieve recovery of movement in a paralysed condition of vocal cords.

The communication was discussed by Sir DAVID FERRIER, Sir FREDERICK MOTT, Dr. W. S. SYME, and Sir W. MILLIGAN.

A large number of clinical cases were shown and discussed.

Otological and Rhinological Problems in Scarlet Fever and Measles.

Mr. T. B. LAYTON initiated a discussion on this topic. One of the chief problems he mentioned was that presented by the child who, after convalescing from scarlet fever, still had a discharge from the ear. Was there a risk that such a child would infect others when he again went into the community? If so, one was faced with either having to keep the child in the fever hospital for a considerable time, or doing an operation on him. The question of the carrier in nose and ear disease was one which would have to be faced in the near future. With regard to mastoiditis in scarlet fever, most authorities considered there was no need for great anxiety concerning extension of disease from bone to the meninges. Much the same problems were presented in measles patients, but as fewer cases of this disease were taken into fever hospitals, there were fewer opportunities of studying them. Sinusitis he did not regard as very common during infectious diseases.

Dr. KERR LOVE said that as an aid to treatment, tonsils and adenoids should be removed as soon as it was safe to do so—i.e., after the fever had subsided. The school authorities should not readmit a child with a running ear after an attack of either scarlet fever or measles. He believed that suggestions would be adopted by the County of Dumbarton and the City of Glasgow authorities.—Sir WILLIAM MILLIGAN said the time to take concerted action on this most important matter to the rising generation was long overdue. These destructive processes in the ear were a great handicap. Adenoids should be removed during the disease—i.e., as soon as the temperature came down; the removal should not be deferred until the patient was convalescent.—Mr. J. ADAM said that of 62 cases who developed otitis media only five required mastoid operation, which seemed to show that the tendency was for otitis media to get well if no operation was done.—Dr. MCKENZIE thought the mastoid should be operated upon more frequently in these cases of discharging ears. The question of secondary paracentesis should never arise.—Mr. NEIL MACLAY said that out of the large number of cases of scarlet fever admitted to the Newcastle Fever Hospital he had never seen the large devastating perforations which were described in the text-books. It was very difficult to anticipate the discharge by paracentesis, but efforts were made to cleanse mouth, fauces, and ears. Tonsils and adenoids, if prominent, were removed at an early period. Mr. J. S. FRASER agreed with Dr. McKenzie as to secondary paracentesis; he had never seen a secondary paracentesis do any good. He believed that if the rhinitis resulting from scarlet fever and measles were cured, much ozæna would be obviated in the future.—The discussion was continued by Mr. HUGH JONES, Dr. SYDENHAM, Mr. BANKS-DAVIS, Mr. GILLESPIE, Dr. F. W. HARTOG, Dr. A. D. SHARP, and Mr. J. F. O'MALLEY, and Mr. LAYTON replied.

Dr. P. WATSON-WILLIAMS read a paper on the Clinical Importance of Nasal Sinus Infection in Mastoiditis.

Dr. ALBERT A. GRAY gave a demonstration of stereoscopic slides for teaching purposes. Coloured representations of minute anatomy could be seen in three dimensions by means of simple two-colour (red and green) spectacle frames worn by the observers.

SECTION OF UROLOGY.

POLYCYSTIC DISEASE OF THE KIDNEY.

A MEETING of this section was held on June 26th, Dr. LANGDON BROWN, the President, being in the chair, when Dr. PARKES WEBER read a paper on the

So-called Myelin Kidney.

He explained that his interest was originally aroused in this subject by the numerous examples of opaque specks and streaks seen in the routine work of the post-mortem room. Some of these streaks were shown to be minute adenomata, others small cysts with intracystic papillary growths; one was a minute true lipoma, and there were many other types. Small deposits of calcium salts and fats were not uncommon, and there occurred not infrequently the deposition of the cholesterin ester named myelin by Virchow. In these cases there were collections of large clear cells in the interstitial part of the kidney cortex. In paraffin sections these cells have a small pyknotic nucleus and faint outlines of a supporting framework can be seen, for which reason they have been termed "foamy" cells. When cut fresh and stained with Sudan III., these cells are stained a brownish pink colour, due to the presence of an anisotropic lipoid as shown by crossed Nicol prisms. In his opinion these cells were similar to those seen in the cutaneous xanthomata. The so-called myelin kidneys occurred in those patients who had a mixed parenchymatous and interstitial nephritis. Either there had been a primary parenchymatous condition followed by a chronic interstitial nephritis, or a glomerular nephritis had been succeeded by the other changes. They were also occasionally found in connexion with chronic endocarditis. The possible prognostic significance of myelin casts in the urine had been emphasised by Dr. McNee following Monck's work in 1913. In this connexion it was to be remembered that cholesteræmia might be present. He pointed out that experimentally myelin kidneys had been produced by feeding rabbits on cholesterin.

Dr. J. W. **McNEE** said that all degrees of this condition existed, from the slight speckling to the gross deposits in the cortex. The term was used to denote a special form of degeneration, which he had found to occur not only in nephritis but in the early stages of arterio-sclerosis, and in some surgical conditions—e.g., chronic mastitis. He believed that the change starts in the tubules, and that some of the fat is excreted as lipoid casts in the urine, and the rest goes via the lymphatics to the interstitial part of the kidney cortex. He believed that this peculiar type of degeneration represented a stage from which there was no recovery, whereas cells undergoing ordinary fatty degeneration were quite capable of regeneration. He therefore regarded myelin casts in the urine of definite prognostic importance, in that the case was one in which a progressive lesion was present, and the outlook was grave.

Dr. S. C. **DYKE** showed photographs of myelin kidneys through crossed Nicols; in his cases the myelin change was in the cells of the tubules. In all his cases there had been œdema and albuminuria, high cholesterol ester content in the blood, and a low urea concentration. In his opinion there was a close association between œdema and the myelin kidney.

Discussion on Polycystic Kidneys.

Sir **THOMAS HORDER** in opening this discussion based his remarks upon three personal cases.

CASE 1.—A man aged 43, when first seen had vomiting and diarrhœa, having had a similar attack over a year before. There was giddiness, with headaches, pains in the back, thirst, and polyuria. Some tingling sensations in the hands and legs were present, and just before being seen he had had a transient swelling of the face and legs each morning. Abdominal examination revealed two large renal swellings. For the first three days there was some pyrexia, the urine was diminished in quantity with some albuminuria. The urine output soon returned to within normal limits,

CASE 3.—A man aged 53, had had persistent vomiting for two years, and was first seen with anorexia, headaches, and urinous smelling breath. The urine was of low specific gravity, was not diminished in amount, and had a low urea concentration. The vomitus contained urea. His retinæ were unchanged, and the abdominal examination revealed bilateral renal swellings of typical character. Vomiting continued and patient died shortly after admission from uræmia with convulsions.

Sir Thomas Horder considered that these cases did nothing more than confirm the generally accepted views on the behaviour of the polycystic kidney. Patients usually came for advice when between 30 and 50, either for chronic renal disease, whether uræmic or cardio-vascular, or because of abdominal swellings. Their course was slow and subject to intercurrent renal nephritis. Unilateral cases would often live for a long time, and his difficulty was to define whether, in those cases of an unilateral swelling, the opposite kidney was unaffected or already cystic, for it was well recognised that one kidney might enlarge several years after the first. He concluded that surgery was not indicated unless the other kidney was normal or unless there were such severe pressure symptoms as to demand relief. He had come across no instances of this being a familial disease, nor had he seen any associated congenital deformities such as hare-lip, talipes equino-varus, &c.

Sir **BERNARD SPILSBURY** gave a complete account of three recent cases brought to post mortem at St. Bartholomew's Hospital.

CASE 1, under the care of Sir Percival Hartley, a man aged 52—had had chronic renal disease for many years, for which he had been invalided from the army. Two weeks before death he was seized with an attack of giddiness which passed into unconsciousness. On admission he had a left hemiplegia, frequency of micturition, and headache. Post-mortem examination showed a small hæmorrhage in the right internal capsule with advanced atheroma of the arteries at the base of the brain, and a cystic condition of both kidneys and of the liver. The liver weighed 50 oz., and scattered through it were a large number of small cysts. Otherwise the organ appeared normal. The kidneys were typical. Microscopically, the liver cysts were lined by a cubical epithelium, and there was pressure atrophy of the liver tissue around the cysts, suggesting that the cysts were actively enlarging. In addition there was a considerable quantity of proliferating bile-ducts through the liver and under its capsule. The kidney cysts were lined with cubical and at times columnar epithelium, and contained hyaline material, necrotic cells, and débris. Dense fibrous tissue riddled the kidney tissue in which there was evidence of marked hypertrophy. In a few of the cysts papillomatous growths were seen. The arteries of these kidneys showed arterio-sclerosis.

CASE 2, under the care of Mr. McAdam Eccles, was a man aged 47. In 1914 this patient was operated on for a suspected pyonephrosis. During the last few months the pain had recurred and there was progressive weakness. The urine contained blood and pus. A large tumour was present, and the case died with signs of uræmia. Post-mortem examination showed atheroma of the aorta; liver enlarged to 72 oz. and containing many cysts; both kidneys enlarged and cystic, and pyelitis in the left; and left suprarenal hypertrophied. Microscopically, liver and kidneys similar to Case 1, save that no proliferating bile-ducts were seen in this liver. Pus and *B. coli* were found in some of the kidney cysts.

CASE 3.—This was Sir Thomas Horder's third case described above. Po[illegible]rtem showed aortic atheroma, liver enlarged with [illegible] eys very much enlarged, and both suprarenals h[illegible]. Microscopically, the liver contained proliferat[illegible]ts, and the kidneys showed [illegible]e amyloid char[illegible]e this case corresponded liver cysts were also due to an excess development of bile-ducts, some of which did not join up with the liver tissue. These livers showed no signs of inflammation or cirrhosis.

The PRESIDENT opened the discussion by commenting on the absence of any mention of hæmaturia as a symptom. He quoted two cases in which this had been present, one being of particular interest because a smart hæmaturia occurred at the age of 30, after which the patient had been passed as a first-class life for insurance. He had seen no associated congenital defects in any of his cases.

Dr. GRAHAM FORBES said that this question was of great interest to him as it had formed the subject of his M.D. thesis very many years ago. During the 25 or more years that had elapsed, he had found nothing of any interest to add to what he had then written. Dr. Forbes read extracts of some of the salient features of the cases he had collected at that time.

Mr. SWIFT JOLY described a case of a man with hæmaturia and a swelling in the right renal region. Cystoscopy showed the blood coming from the right ureter. The diagnosis made was malignant growth of the right kidney, which was exposed. It turned out to be a polycystic kidney and the wound was closed. Three years later that man had another hæmaturia, and cystoscopy revealed blood coming from the left ureter, and that kidney was enlarged. With regard to the familial incidence, one patient had consulted him with bilateral polycystic kidneys, saying that he was one of five brothers, all of whom had congenital cystic kidney. He did not believe that there were any indications for nephrectomy. Surgery did no good but harm. He was anxious to hear if any surgeon had tried pyelography in these cases. He had found that the shadow of the pelvis, though normal in appearance with no flattening of the calyces, yet had a very long calyx system. One of his cases the length was quite four times the normal. He suggested that this affords an early diagnostic criterion.

Mr. GIRLING BALL recalled a case of a child who died of polycystic kidney following an operation for genu valgum; also another child who died during measles from the polycystic kidney. He had recently in Berne watched de Quervain operate on one of these cases, by cutting a slice—like a slice of a lemon—out of the kidney. He claimed that fibrosis followed, and improvement in the patient. Mr. Ball was somewhat sceptical concerning the value of this operation.

Mr. C. A. R. NITCH said that he had always thought the infantile and the adult type of case were of different ætiology, and he asked Sir Bernard Spilsbury how he reconciled the one view for the two classes of case.

Sir THOMAS HORDER and Sir BERNARD SPILSBURY replied to the discussion, both commenting on the value of Mr. Joly's suggestion of pyelography in diagnosis, and in reply to Mr. Nitch pointing out that the same process was involved, the change being only a matter of degree.

PARIS: VACATION COURSE IN DISEASES OF CHILDREN.—A vacation course in diseases of children will be given at the Hôpital des Enfants Malades, 149, Rue de Sèvres, Paris, from July 24th to August 14th, under the direction of Prof. Nobecourt and Dr. Lereboullet. There will be two meetings each day, at 10.30 A.M. and 4 P.M., and Prof. Nobecourt will give clinical instruction every morning at 9.15. The fee for the course is Fr.150. A detailed programme may be obtained from the Faculté de Médecine, University of Paris.

A course of 13 sessions on the treatment of tuberculosis of the bones, joints, and ganglia, together with methods of practical orthopædics, will be given at the Hôpital Maritime, Berck-plage, from July 15th to 30th. The course will be conducted by Dr. E. Sorrel, surgeon to the hospitals of Paris and chief surgeon to the Marine Hospital of Berck, assisted by Drs. Moyer and Parin, of the Maritime Hospital Laboratory, Dr. Lance, of the Sick Children's Hospital, and others. The meetings will be held in the afternoons at 2 o'clock. The fee for the course is Fr.150. Full particulars may be obtained from Dr. Sorrel, 46, Rue du Général Foy, Paris.

EPIDEMIC ENCEPHALITIS.

Encephalitis Lethargica. By ARTHUR J. HALL, M.A., M.D. Camb., F.R.C.P. Lond., Professor of Medicine, University of Sheffield. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.; Bristol: John Wright and Sons, Ltd. 1924. Pp. 229. 12*s*.

THE greater part of this work formed the Lumleian Lectures delivered before the Royal College of Physicians of London in 1923 and published in abridged form in THE LANCET of April 14th, 1923. The additions made in the present volume comprise details which could not be included within the limits of the lectures, references to more recent studies and experiences since their delivery, and a section on treatment.

It was on April 20th, 1918, that Prof. Hall and Dr. Wilfred Harris independently announced in the same number of THE LANCET that within the previous fortnight a series of cases of illness presenting remarkable features had appeared in this country. Prof. Hall, although he characteristically omits to do so, can therefore claim the merit of being one of the first to detect the "new disease"; his careful notes and records of the early cases of encephalitis contributed in no small degree to the clinical presentation of the outbreak of 1918. Since then his published writings have added to our knowledge of the malady whose epidemic prevalence this year in Great Britain on an unprecedented scale makes the appearance of this book all the more timely. For the purpose of the lectures Prof. Hall has read widely. The lengthy bibliography, in main that of the Ministry of Health's Report on Encephalitis Lethargica, published in 1922, but extended and brought up to the present time by the author, numbers no less than 2056 references. It becomes almost the task of a life-time to keep well abreast of the literature of epidemic encephalitis. Indeed, it is here that we would make the most serious criticism of Prof. Hall's book. If anything, he has been too generous towards the experience and views of others and too restricted in the expression of his own. To take an example at random, in alluding to the hæmorrhagic syndrome, the writings of physicians in England, France, and America are referred to in some detail; but Prof. Hall's personal knowledge of the subject is not allowed to appear. We would also express the hope that in future editions the author will give us more instruction from his case-books; the few cases he quotes only serve to whet the reader's appetite. In Chapter IV. Prof. Hall tells us that he has been so impressed by the protean manifestations of the disease that he finds it impossible to recognise any regular distinction beyond the broader divisions of acute and chronic. Accordingly he gives no set description of the malady, but an account of the clinical manifestations that may be encountered. It is true that these are the forms which most frequently come to the attention of the consulting neurologist, yet the characteristics of epidemic encephalitis as a general infectious disease must not be ignored. The prodromal period and the onset of pyrexia too often escape recognition as part and parcel of the one disease, even although nervous localising signs appear subsequently. Further, the general features of epidemic encephalitis are in harmony with the description of the allied disease, epidemic poliomyelitis. A brief but useful account of the later manifestations of epidemic encephalitis is given. As regard treatment, the author's melancholy verdict is that "at present any reliable therapeusis, either for the disease itself or for its many after-results, does not exist."

The work constitutes a comprehensive treatise on epidemic encephalitis which neither neurologist nor general physician can afford to exclude from his book-shelf. It is well illustrated by a number of plates, with intracystic papillary growths; one was a minute true lipoma, and there were many other types. Small deposits of calcium salts and fats were not uncommon, and there occurred not infrequently the deposition of the cholesterin ester named myelin by Virchow. In these cases there were collections of large clear cells in the interstitial part of the kidney cortex. In paraffin sections these cells have a small pyknotic nucleus and faint outlines of a supporting framework can be seen, for which reason they have been termed "foamy" cells. When cut fresh and stained with Sudan III., these cells are stained a brownish pink colour, due to the presence of an anisotropic lipoid as shown by crossed Nicol prisms. In his opinion these cells were similar to those seen in the cutaneous xanthomata. The so-called myelin kidneys occurred in those patients who had a mixed parenchymatous and interstitial nephritis. Either there had been a primary parenchymatous condition followed by a chronic interstitial nephritis, or a glomerular nephritis had been succeeded by the other changes. They were also occasionally found in connexion with chronic endocarditis. The possible prognostic significance of myelin casts in the urine had been emphasised by Dr. McNee following Monck's work in 1913. In this connexion it was to be remembered that cholesteræmia might be present. He pointed out that experimentally myelin kidneys had been produced by feeding rabbits on cholesterin.

Dr. J. W. McNee said that all degrees of this condition existed, from the slight speckling to the gross deposits in the cortex. The term was used to denote a special form of degeneration, which he had found to occur not only in nephritis but in the early stages of arterio-sclerosis, and in some surgical conditions—e.g., chronic mastitis. He believed that the change starts in the tubules, and that some of the fat is excreted as lipoid casts in the urine, and the rest goes via the lymphatics to the interstitial part of the kidney cortex. He believed that this peculiar type of degeneration represented a stage from which there was no recovery, whereas cells undergoing ordinary fatty degeneration were quite capable of regeneration. He therefore regarded myelin casts in the urine of definite prognostic importance, in that the case was one in which a progressive lesion was present, and the outlook was grave.

Dr. S. C. Dyke showed photographs of myelin kidneys through crossed Nicols; in his cases the myelin change was in the cells of the tubules. In all his cases there had been œdema and albuminuria, high cholesterol ester content in the blood, and a low urea concentration. In his opinion there was a close association between œdema and the myelin kidney.

Discussion on Polycystic Kidneys.

Sir Thomas Horder in opening this discussion based his remarks upon three personal cases.

Case 1.—A man aged 43, when first seen had vomiting and diarrhœa, having had a similar attack over a year before. There was giddiness, with headaches, pains in the back, thirst, and polyuria. Some tingling sensations in the hands and legs were present, and just before being seen he had had a transient swelling of the face and legs each morning. Abdominal examination revealed two large renal swellings. For the first three days there was some pyrexia, the urine was diminished in quantity with some albuminuria. The urine output soon returned to within normal limits, the albumin disappeared, but the blood-urea remained high. Urea concentration in the urine was on four occasions 1 per cent., 1·1 per cent., 1·1 per cent., and 1·15 per cent. Diagnosis was bilateral polycystic kidney, and the man is alive to-day, some two years after.

Case 2.—A woman aged 34, came for advice because of a large abdominal tumour two months after her second normal pregnancy. The gynæcologist who saw her believed the tumour to be coming from the pelvis, and thought it an ovarian cyst. Laparotomy revealed a left polycystic kidney, which was removed. The right kidney was slightly enlarged to the examining hand, and the pelvic organs normal. Afterwards she developed an acute coli infection of the urine, which subsided afterwards. Patient alive and well two and a half years later.

Case 3.—A man aged 53, had had persistent vomiting for two years, and was first seen with anorexia, headaches, and urinous smelling breath. The urine was of low specific gravity, was not diminished in amount, and had a low urea concentration. The vomitus contained urea. His retinæ were unchanged, and the abdominal examination revealed bilateral renal swellings of typical character. Vomiting continued and patient died shortly after admission from uræmia with convulsions.

Sir Thomas Horder considered that these cases did nothing more than confirm the generally accepted views on the behaviour of the polycystic kidney. Patients usually came for advice when between 30 and 50, either for chronic renal disease, whether uræmic or cardio-vascular, or because of abdominal swellings. Their course was slow and subject to intercurrent renal nephritis. Unilateral cases would often live for a long time, and his difficulty was to define whether, in those cases of an unilateral swelling, the opposite kidney was unaffected or already cystic, for it was well recognised that one kidney might enlarge several years after the first. He concluded that surgery was not indicated unless the other kidney was normal or unless there were such severe pressure symptoms as to demand relief. He had come across no instances of this being a familial disease, nor had he seen any associated congenital deformities such as hare-lip, talipes equino-varus, &c.

Sir Bernard Spilsbury gave a complete account of three recent cases brought to post mortem at St. Bartholomew's Hospital.

Case 1, under the care of Sir Percival Hartley, a man aged 52—had had chronic renal disease for many years, for which he had been invalided from the army. Two weeks before death he was seized with an attack of giddiness which passed into unconsciousness. On admission he had a left hemiplegia, frequency of micturition, and headache. Post-mortem examination showed a small hæmorrhage in the right internal capsule with advanced atheroma of the arteries at the base of the brain, and a cystic condition of both kidneys and of the liver. The liver weighed 50 oz., and scattered through it were a large number of small cysts. Otherwise the organ appeared normal. The kidneys were typical. Microscopically, the liver cysts were lined by a cubical epithelium, and there was pressure atrophy of the liver tissue around the cysts, suggesting that the cysts were actively enlarging. In addition there was a considerable quantity of proliferating bile-ducts through the liver and under its capsule. The kidney cysts were lined with cubical and at times columnar epithelium, and contained hyaline material, necrotic cells, and débris. Dense fibrous tissue riddled the kidney tissue in which there was evidence of marked hypertrophy. In a few of the cysts papillomatous growths were seen. The arteries of these kidneys showed arterio-sclerosis.

Case 2, under the care of Mr. McAdam Eccles, was a man aged 47. In 1914 this patient was operated on for a suspected pyonephrosis. During the last few months the pain had recurred and there was progressive weakness. The urine contained blood and pus. A large tumour was present, and the case died with signs of uræmia. Post-mortem examination showed atheroma of the aorta; liver enlarged to 72 oz. and containing many cysts; both kidneys enlarged and cystic, and pyelitis in the left; and left suprarenal hypertrophied. Microscopically, liver and kidneys similar to Case 1, save that no proliferating bile-ducts were seen in this liver. Pus and *B. coli* were found in some of the kidney cysts.

Case 3.—This was Sir Thomas Horder's third case described above. Post-mortem showed aortic atheroma, liver enlarged with cysts, kidneys very much enlarged, and both suprarenals hypertrophied. Microscopically, the liver contained proliferating bile-ducts, and the kidneys showed some amyloid change, otherwise this case corresponded closely to the others.

Sir Bernard Spilsbury summed up these cases as showing very similar kidney conditions with arterio-sclerosis, signs of chronic interstitial nephritis, hypertrophy of the heart, and aortic atheroma, and two of them suprarenal hypertrophy. The age at which these patients died was the same period at which occurred deaths from chronic interstitial nephritis. He had no doubt at all that the origin of the polycystic kidney was in some anomaly of development. He regarded the renal inadequacy as due to superimposed nephritis and not due to pressure of the cysts in the renal tissue. He believed that the liver cysts were also due to an excess development of bile-ducts, some of which did not join up with the liver tissue. These livers showed no signs of inflammation or cirrhosis.

The PRESIDENT opened the discussion by commenting on the absence of any mention of hæmaturia as a symptom. He quoted two cases in which this had been present, one being of particular interest because a smart hæmaturia occurred at the age of 30, after which the patient had been passed as a first-class life for insurance. He had seen no associated congenital defects in any of his cases.

Dr. GRAHAM FORBES said that this question was of great interest to him as it had formed the subject of his M.D. thesis very many years ago. During the 25 or more years that had elapsed, he had found nothing of any interest to add to what he had then written. Dr. Forbes read extracts of some of the salient features of the cases he had collected at that time.

Mr. SWIFT JOLY described a case of a man with hæmaturia and a swelling in the right renal region. Cystoscopy showed the blood coming from the right ureter. The diagnosis made was malignant growth of the right kidney, which was exposed. It turned out to be a polycystic kidney and the wound was closed. Three years later that man had another hæmaturia, and cystoscopy revealed blood coming from the left ureter, and that kidney was enlarged. With regard to the familial incidence, one patient had consulted him with bilateral polycystic kidneys, saying that he was one of five brothers, all of whom had congenital cystic kidney. He did not believe that there were any indications for nephrectomy. Surgery did no good but harm. He was anxious to hear if any surgeon had tried pyelography in these cases. He had found that the shadow of the pelvis, though normal in appearance with no flattening of the calyces, yet had a very long calyx system. One of his cases the length was quite four times the normal. He suggested that this affords an early diagnostic criterion.

Mr. GIRLING BALL recalled a case of a child who died of polycystic kidney following an operation for genu valgum; also another child who died during measles from the polycystic kidney. He had recently in Berne watched de Quervain operate on one of these cases, by cutting a slice—like a slice of a lemon—out of the kidney. He claimed that fibrosis followed, and improvement in the patient. Mr. Ball was somewhat sceptical concerning the value of this operation.

Mr. C. A. R. NITCH said that he had always thought the infantile and the adult type of case were of different ætiology, and he asked Sir Bernard Spilsbury how he reconciled the one view for the two classes of case.

Sir THOMAS HORDER and Sir BERNARD SPILSBURY replied to the discussion, both commenting on the value of Mr. Joly's suggestion of pyelography in diagnosis, and in reply to Mr. Nitch pointing out that the same process was involved, the change being only a matter of degree.

PARIS: VACATION COURSE IN DISEASES OF CHILDREN.—A vacation course in diseases of children will be given at the Hôpital des Enfants Malades, 149, Rue de Sèvres, Paris, from July 24th to August 14th, under the direction of Prof. Nobecourt and Dr. Lereboullet. There will be two meetings each day, at 10.30 A.M. and 4 P.M., and Prof. Nobecourt will give clinical instruction every morning at 9.15. The fee for the course is Fr.150. A brief but useful account of the later manifestations of epidemic encephalitis is given. As regard treatment, the author's melancholy verdict is that "at present any reliable therapeusis, either for the disease itself or for its many after-results, does not exist."

The work constitutes a comprehensive treatise on epidemic encephalitis which neither neurologist nor general physician can afford to exclude from his book-shelf. It is well illustrated by a number of plates,

Laboratory Diagnosis of Syphilis.

A Manual for Students and Physicians. By Hideyo Noguchi, M.D., Ph.D., D.Sc., Member of the Rockefeller Institute for Medical Research, New York. London: Humphrey Milford. 1923. Pp. 392. 36s.

The author considers that the laboratory procedures for the diagnosis of syphilis falls into two groups: (a) the detection of the causative spirochæte, (b) the detection of certain pathological changes produced in the tissues by the micro-organism. In the first group he believes that the dark-ground illumination is the most reliable method of demonstrating the spirochæte of syphilis, and most workers on this subject will agree with him. The chapter on microscopical technique gives many hints and much useful information with regard to dark-ground apparatus and its manipulation. We would point out that no indication is given that a high dry lens (3 mm.) with a correction collar gives as good, if not better, results than an oil-immersion lens, and, in addition, is easier to handle. The various staining methods, negative and positive, are fully dealt with, including many very recent procedures. The excellent photographs in this section of the book should prove very helpful in enabling laboratory workers to gain a thorough idea of the morphology of the various spirochætes likely to be encountered in material suspected of containing the *Treponema pallidum*.

The greater part of the volume is concerned with the sero-diagnosis of syphilis (Wassermann test). The introductory chapters give a satisfactory account of the theory of the fixation of the complement test. The main idea of the remainder of this section is to show the advantages of the author's method, using an acetone-insoluble antigen and an anti-human hæmolytic system. It cannot be said, however, that considering the tested accuracy of the Wassermann as done by modern standardised technique the author has brought much evidence to support his contention. The relative value of Wassermann methods is not a matter of opinion but of actual results, and the author's arguments without comparative tests are not sufficient to convince that his method is more reliable than the ordinary test. In fact, many sound objections could be urged against his method both from the technical and theoretical side; for instance, against the use of 2 units of amboceptor, of an acetone-insoluble antigen, and especially the failure to titrate complement in the presence of antigen before each test. As in many American books, the account of British literature is incomplete; for instance, there is no mention of any of the valuable series of reports published by the Medical Research Council on the Wassermann test and its reliability.

Le Problème de l'Anaphylaxie.

By Auguste Lumière. Paris: Gaston Doin. 1924. Pp. 241. Fr.30.

This book deals with the problem of anaphylaxis from the latest physico-chemical point of view of the colloid. The introductory chapter reviews the subject historically in clear narrative fashion, but the bulk of the book is devoted to the modern physical conception of anaphylaxis. The author starts from the well-known Tyndall experiment on colloids and leads up to the work of Dold who has applied the principles of Tyndall in the seroscope. From this point onwards he shows step by step how the anaphylactic phenomena result from the alteration in the colloidal state of the serum of the sensitised animal brought into contact with the antigen, and he rejects, in consequence, the theory of a chemical toxic factor, believed in by the older experimenters. This alteration in the colloidal state of the serum—to use the author's own words, " la formation d'un floculat dans le sérum "—is, in the author's opinion, responsible for the anaphylactic shock by acting on nerve terminations of the endothelium of the vessels supplying the nerve centres. By this means sudden excitation of these centres produces in turn vaso-dilatation of the visceral blood-vessels and a fall of arterial pressure. Various blood changes then follow apparently as a result of alteration of osmotic pressure.

This, in brief, is the author's theory of anaphylaxis. The separate stages are worked out with logical precision, and a certain number of experiments illustrated with beautifully coloured drawings are given, but the author is led along the paths of theory faster than the facts warrant. Although the colloidal theory of anaphylaxis has much more to be said in its favour than any other, yet there are many difficulties still to be faced which the author does not even mention. There are large and important questions summed up in the terms indirect and secondary anaphylaxis yet to be answered, whilst clinical medicine bristles with points of interest to the serologist still awaiting solution. And whether or no these questions can be answered by the colloidal theory we do not yet know. The author barely mentions the large stock of material accumulated by Chandler Walker and others on protein sensitisation. In our opinion, it is on this particular question that the final test of the theories of anaphylaxis must be made. Hitherto animal experiments have by no means followed the lines of clinical experiments in protein sensitisation as applied to skin tests of asthma and gastro-intestinal disturbances, and there would appear to be still some additional factors in the problem unrecognised. As an exposition of the colloidal theory of anaphylaxis, however, this book is a useful guide, concisely and logically thought out.

Posture.

Körperstellung. By R. Magnus, Professor at the Reichsuniversität, Utrecht. Berlin: J. Springer. 1924. Pp. 740. $6.45.

This work contains in a fairly complete, and therefore somewhat bulky, form an account of the researches of Prof. Magnus and his pupils and colleagues which have earned world-wide fame. After dealing with the subject-matter in its general aspects, the conditions which determine particular reflexes and the maintenance of posture are considered. The chapters on compensatory posture of the eyes, and on the relations of the labyrinth, neck, and eyes to postural tonus, contain a description of some of the finest work in neurology during the present century; the clinical applications of this series of investigations must obviously be very extensive, and some interesting examples are given by way of illustration. The book concludes with a chapter on the influence of various poisons on posture. Taken as a whole, the degree of precision attained is remarkable. This knowledge has been obtained by a variety of methods—by graphic methods, direct observation, surgical experiments on the labyrinths and on the central nervous system, and by large numbers of photographs and cinematograph films. The inclusion among the 263 illustrations of a number of stereoscopic photographic reproductions adds greatly to the value of the publication.

The Science and Art of Anæsthesia.

By Col. W. Webster, M.D. London: Henry Kimpton; St. Louis: C. V. Mosby Co. Illustrated. 1924. Pp. 214 24s.

This book is designed to help " the medical student and the physician in general practice." It is a pleasing manual in size, shape, and excellence of printing. Unfortunately it lacks many of those details which are essential in the instruction of those for whom it is intended. They are nowhere told just what to do in the process of procuring and maintaining anæsthesia. In the physiology of the drugs which he is to use and in some general principles the reader is well instructed, and help is given in these pages as to treatment before and after operation. The author states that he has purposely omitted " plates " showing different positions of patients for different operations, and no one would blame him for that in a work of this size, but he has no fewer than nine pages of illustrations of apparatus for nitrous oxide, and this prodigality appears disproportionate. Few things are less instructive than pictures or diagrams of apparatus. The student can only learn to use apparatus by handling it, and this lesson must be enforced in a small manual. Some of these pages might well be replaced by brief instructions in the treatment of common difficulties and dangers arising during anæsthesia, a subject which the author has almost ignored.

Internal Secretions.

Biology of the Internal Secretions. By Francis X. Dercum, M.D., Ph.D., Professor of Nervous and Mental Diseases in the Jefferson Medical College, Philadelphia. London and Philadelphia: W. B. Saunders Company, Ltd. 1924. Pp. 241. 14s.

In giving us this account, chiefly clinical, of the internal secretions, and especially of their relations to malformations and mental diseases, the author has attempted much. The time is really not yet ripe for such sweeping applications of endocrinology, as events will no doubt prove. But if we keep the limitations constantly in mind the book should provide us with stimulating, if at times rather bewildering, reading, though its value would have been considerably increased if precise references to the authors quoted had been given. By those eager to investigate the possibilities of the clinical application of endocrinology, and their number is rapidly increasing, these pages will be read with interest.

Sexualité et Hormones. By Ch. Champy, Docteur en Médecine, Docteur ès Sciences, Professeur Agrégé à la Faculté de Médecine de Paris. Paris: Octave Doin. 1924. Pp. 372. Fr.30.

In this interesting volume much of the discussion turns on the facts of secondary sexual characters and of the conditions which bring about their modification. The author considers the influence of hormones on sexual differentiation, with especial reference to the effect of the thyroid, which has been well investigated, and of the hormones arising in the gonads themselves. The localisation of the sex hormones exclusively in any one tissue, such as the interstitial tissue of the gonads, is considered to be without justification. The volume is well illustrated, contains the results of a large amount of original work, and displays much careful thought.

Atlas of Diseases of the Chest.

Thoraxschnitte von Erkrankungen Der Brustorgane. By Dr. Walter Koch, Professor of Pathological Anatomy, Berlin. Berlin: Julius Springer. 1924. Pp. 403. $10.75.

While it is generally acknowledged that the physician's art should be built up on a basis of morbid anatomy, it is not so well realised how difficult it is for the majority of medical students to obtain a practical first-hand knowledge of topographical morbid anatomy. They may have demonstrated to them diseased organs which have been removed from the body, but unless time is of no object and classes are small, it is scarcely possible for them to study completely and at leisure the organs while still in the body. The same routine cannot well be adopted in the study of morbid anatomy as obtains in the dissecting room, and in consequence it is really difficult for the student to appreciate the meaning and importance of the lesions he is taught to recognise in the isolated organ. Only the individual who actually removes the viscera from the thorax in, for example, a case of pulmonary tuberculosis can fully understand the significance of the physical signs which may have been elicited during life. The teacher of morbid anatomy who recognises the limitations imposed on him by the exigencies of the medical curriculum will welcome Dr. Koch's excellent atlas. In it some 30 examples of the more chronic pulmonary diseases—pleurisy, phthisis, valvular lesions of the heart, aneurysm of the aorta, new growths, and so forth—are described and illustrated by full-page photographs of vertical sections of the thorax at different antero-posterior levels. Each figure is accompanied by an outline "key," and each case is rendered complete by the inclusion of clinical and post-mortem protocols, and a general summary or discussion. There are also admirable X ray photographs of several of the cases, which are clear and beautifully reproduced, and fulfil their purpose excellently. The Atlas should be a real help to the student in enabling him to understand more truly the actual physical condition of his patients.

Chemical Encyclopædia.

By C. T. Kingzett. London: Baillière, Tindall and Cox. 1924. Pp. 606. 30s.

To compile an ideal chemical encyclopædia would be an impossible task. The present volume is suitable for schools, junior students, and general readers as a book of reference. To the laboratory worker it is of little value, since too little information is given. The contents are remarkably complete with regard to the number of substances referred to, but there is not enough descriptive matter. A better title would have been A Chemical Dictionary.

Biochemistry.

The Vegetable Proteins. Second edition. By Thomas B. Osborn, Ph.D. London: Longmans, Green and Co. 1924. Pp. 154. 9s.

The first edition of Dr. Osborn's book was regarded as one of the standard works upon the subject of vegetable proteins. The advances in this particular branch of biochemistry have been greater perhaps than in any other part, and many of these advances have originated from Dr. Osborn's own laboratory. The importance of the chemical constitution of vegetable proteins in relation to animal feeding has long been recognised, and it is mainly to the researchers in agricultural chemistry that we owe the recent increase in our knowledge. The monograph commences with an historical summary of the subject, and then proceeds to a detailed account of the classification, occurrence, composition, and chemical and physiological properties of the vegetable proteins, while two useful chapters are included on the nutritive value and on the physiological relations of the vegetable proteins to animal organisms. A full account of anaphylaxis in connexion with these bodies is given. An important chapter on the relation of the proteins to acids and bases has been provided by Prof. L. J. Henderson. The volume will prove of great use to all working on this particular branch of biochemistry.

Analyses de chimie biologique. By Rene Clogne. Paris: Le François. 1924. Pp. 281. Fr.14.

The French manuals on practical biochemistry usually strike those accustomed to reading many books of a similar character as being very much out of date. The methods described are too often slight modifications of those in use 30 or 40 years ago, and it is seldom that the newest methods are included. This volume forms a pleasant exception, since it contains workable descriptions of such methods as those of Folin and Wu, Marriot and P. A. Shaffer. What is more, it is obvious that these methods have not been simply copied from other text-books, for the printer's errors in connexion with Folin's methods are not repeated with that dismal regularity with which they unfortunately appear in many of the English manuals. The working descriptions of all the methods described are clear, accurate, and concise, and the scope of the book is sufficiently wide to cover all the needs of students or a routine laboratory. The author is to be congratulated upon his work.

LABORATORY DIAGNOSIS OF SYPHILIS.

A Manual for Students and Physicians. By HIDEYO NOGUCHI, M.D., Ph.D., D.Sc., Member of the Rockefeller Institute for Medical Research, New York. London: Humphrey Milford. 1923. Pp. 392. 36*s*.

THE author considers that the laboratory procedures for the diagnosis of syphilis falls into two groups: (*a*) the detection of the causative spirochæte, (*b*) the detection of certain pathological changes produced in the tissues by the micro-organism. In the first group he believes that the dark-ground illumination is the most reliable method of demonstrating the spirochæte of syphilis, and most workers on this subject will agree with him. The chapter on microscopical technique gives many hints and much useful information with regard to dark-ground apparatus and its manipulation. We would point out that no indication is given that a high dry lens (3 mm.) with a correction collar gives as good, if not better, results than an oil-immersion lens, and, in addition, is easier to handle. The various staining methods, negative and positive, are fully dealt with, including many very recent procedures. The excellent photographs in this section of the book should prove very helpful in enabling laboratory workers to gain a thorough idea of the morphology of the various spirochætes likely to be encountered in material suspected of containing the *Treponema pallidum*.

The greater part of the volume is concerned with the sero-diagnosis of syphilis (Wassermann test). The introductory chapters give a satisfactory account of the theory of the fixation of the complement test. The main idea of the remainder of this section is to show the advantages of the author's method, using an acetone-insoluble antigen and an anti-human hæmolytic system. It cannot be said, however, that considering the tested accuracy of the Wassermann as done by modern standardised technique the author has brought much evidence to support his contention. The relative value of Wassermann methods is not a matter of opinion but of actual results, and the author's arguments without comparative tests are not sufficient to convince that his method is more reliable than the ordinary test. In fact, many sound objections could be urged against his method both from the technical and theoretical side; for instance, against the use of 2 units of amboceptor, of an acetone-insoluble antigen, and especially the failure to titrate complement in the presence of antigen before each test. As in many American books, the account of British literature is incomplete; for instance, there is no mention of any of the valuable series of reports published by the Medical Research Council on the Wassermann test and its reliability.

LE PROBLÈME DE L'ANAPHYLAXIE.

By AUGUSTE LUMIÈRE. Paris: Gaston Doin. 1924. Pp. 241. Fr.30.

THIS book deals with the problem of anaphylaxis from the latest physico-chemical point of view of the colloid. The introductory chapter reviews the subject historically in clear narrative fashion, but the bulk of the book is devoted to the modern physical conception of anaphylaxis. The author starts from the well-known Tyndall experiment on colloids and leads up to the work of Dold who has applied the principles of Tyndall in the seroscope. From this point onwards he shows step by step how the anaphylactic phenomena result from the alteration in the colloidal state of the serum of the sensitised animal brought into contact with the antigen, and he rejects, in consequence, the theory of a chemical toxic factor, believed in by the older experimenters. This alteration in the colloidal state of the serum—to use the author's own words, "la formation d'un floculat dans le sérum"—is, in the author's opinion, responsible for the anaphylactic shock by acting on nerve terminations of the endothelium of the vessels supplying the nerve centres. By this means sudden excitation of these centres produces in turn vaso-dilatation of the visceral blood-vessels and a fall of arterial pressure. Various blood changes then follow apparently as a result of alteration of osmotic pressure.

This, in brief, is the author's theory of anaphylaxis. The separate stages are worked out with logical precision, and a certain number of experiments illustrated with beautifully coloured drawings are given, but the author is led along the paths of theory faster than the facts warrant. Although the colloidal theory of anaphylaxis has much more to be said in its favour than any other, yet there are many difficulties still to be faced which the author does not even mention. There are large and important questions summed up in the terms indirect and secondary anaphylaxis yet to be answered, whilst clinical medicine bristles with points of interest to the serologist still awaiting solution. And whether or no these questions can be answered by the colloidal theory we do not yet know. The author barely mentions the large stock of material accumulated by Chandler Walker and others on protein sensitisation. In our opinion, it is on this particular question that the final test of the theories of anaphylaxis must be made. Hitherto animal experiments have by no means followed the lines of clinical experiments in protein sensitisation as applied to skin tests of asthma and gastro-intestinal disturbances, and there would appear to be still some additional factors in the problem unrecognised. As an exposition of the colloidal theory of anaphylaxis, however, this book is a useful guide, concisely and logically thought out.

POSTURE.

Körperstellung. By R. MAGNUS, Professor at the Reichsuniversität, Utrecht. Berlin: J. Springer. 1924. Pp. 740. $6.45.

THIS work contains in a fairly complete, and therefore somewhat bulky, form an account of the researches of Prof. Magnus and his pupils and colleagues which have earned world-wide fame. After dealing with the subject-matter in its general aspects, the conditions which determine particular reflexes and the maintenance of posture are considered. The chapters on compensatory posture of the eyes, and on the relations of the labyrinth, neck, and eyes to postural tonus, contain a description of some of the finest work in neurology during the present century; the clinical applications of this series of investigations must obviously be very extensive, and some interesting examples are given by way of illustration. The book concludes with a chapter on the influence of various poisons on posture. Taken as a whole, the degree of precision attained is remarkable. This knowledge has been obtained by a variety of methods—by graphic methods, direct observation, surgical experiments on the labyrinths and on the central nervous system, and by large numbers of photographs and cinematograph films. The inclusion among the 263 illustrations of a number of stereoscopic photographic reproductions adds greatly to the value of the publication.

THE SCIENCE AND ART OF ANÆSTHESIA.

By Col. W. WEBSTER, M.D. London: Henry Kimpton; St. Louis: C. V. Mosby Co. Illustrated. 1924. Pp. 214 24*s*.

THIS book is designed to help "the medical student and the physician in general practice." It is a pleasing manual in size, shape, and excellence of printing. Unfortunately it lacks many of those details which are essential in the instruction of those for whom it is intended. They are nowhere told just what to do in the process of procuring and maintaining anæsthesia. In the physiology of the drugs which he is to use and in some general principles the reader is well instructed, and help is given in these pages as to treatment before and after operation. The author states that he has purposely omitted "plates"

THE LANCET.

LONDON: SATURDAY, JULY 5, 1924.

MUNICIPAL AND HOME DISINFECTION.

WE publish this week an interesting article by Dr. DUNCAN FORBES, medical officer of health for Brighton, who deals from personal experience with the comparative merits of municipal and home disinfection in scarlet fever and diphtheria. In this paper there is well illustrated the change of opinion which has been going on for 30 years or more in respect of the factors which make for the spread of infection in these two diseases, and Dr. FORBES suggests that much of the elaborate and extravagant procedure which characterised the 'eighties and 'nineties and the first few years of this century was open to the charge of being ill-directed, serving little purpose except to give a fancied security to the householder. The message of the paper, indeed, is that the household, with certain well-directed assistance from the municipality, can obtain usually the same measure of security by personal efforts as by relying upon central assistance, and it need hardly be said that the more the population can help themselves in sanitary matters the better will public health be served.

Until 1909 the usual ritual was followed at Brighton of removing all persons suffering from scarlet fever or diphtheria to the isolation hospital, when thorough disinfection of the home premises was carried out. The process was extended not only to the patient's and the mother's clothing, to mattresses and to bedclothes, but to the contents of wardrobes and chests, while curtains and carpets were removed for steam disinfection and the walls, ceiling, and floor of the room lately occupied by the patient were sprayed with disinfectant. But while this drastic course was still being pursued the opinion was getting stronger that epidemic prevalence was due to personal contact with the case; it was felt that scattered organisms in the premises had no substantial consequence compared to that dependent on the massive doses of organisms to be derived from the patient and from handkerchiefs and towels contaminated by immediate discharges from the carriers. Consequently, in 1909, the steam disinfection of the bedding and mattresses was stopped at Brighton, and instructions were given to householders for the immediate and proper cleansing of linen and cotton goods which had been in contact with the sick subject and for the disinfection by boiling water of all feeding and drinking utensils, toys, books, and other articles which had been in the patient's immediate environment. Eleven years later procedure was further simplified when the spraying of the sick-room was given up, cleansing and the accompanying disinfection being left to the householder. Dr. FORBES's paper contains a short series of figures—too short, as he admits, to constitute absolute proof of any contention—showing that at Brighton disinfection by the local authority has presented no advantage over disinfection by the housewife.

Dr. FORBES's conclusions have been submitted by us to the medical officers of health of certain large and representative cities with the result that we find the main contentions to be substantially endorsed, with certain individual reservations due to differences of locality. But if disinfection of houses in cases of scarlet fever and diphtheria is found to be unnecessary, some of the contracts entered into by big municipalities may be an extravagance, and this is a matter which needs consideration, if only to prevent the hasty conclusion that vast and unwarranted expenditure is taking place. The Corporation of London puts down in its form for tender a probable annual requirement of 5000 gallons of disinfectant fluid of high coefficiency as well as 20 named disinfectants in fluid or powder form. Clearly no substantial proportion of these commodities is required for spraying infected chambers. It is not possible to compare accurately the bulk and cost of the disinfectants and chemicals used in various health departments because no two health departments cover quite the same ground, nor do they use the same solutions, nor apparently do they spend money in this way in any amount proportionate to the population. One progressive city, for example, with a population of nearly 1,000,000, used or gave out disinfectants from its public health department to the value of £163 for the financial year ending March 31st, 1924, a figure which shows that here no extravagance was committed. The disinfectants are used for a vast number of purposes, and non-employment in spraying premises where scarlet fever or diphtheria patients have resided would lead to little annual diminution in expense to the ratepayers. And the moral value of using disinfectants, probably not so needed in a city like Brighton as in cities where there is a great slum population to deal with, must not be left out of count.

◆

ARTIFICIAL LIMBS.

A MEETING of representatives of associations of disabled men of Austria, France, Germany, Great Britain, Italy, and Poland met at Geneva in 1921 and appealed to the International Labour Office to help to further the production of appliances for the benefit of the mutilated and to spread a knowledge of them. The office, which is connected with, but not a part of, the League of Nations, accordingly asked Dr. FLORENT MARTIN to compile a report which should set forth what has been done in all countries to provide prostheses and other appliances for the disabled with a view to helping not only sufferers in the late war, but also those whose injuries were received in civil life. Dr. MARTIN was well known during the war as the director of the artificial limb factory at La Panne, in Belgium, where, under his direction, was made an artificial leg, the merits of which he strongly advocated. He is now director of the Technical and Scientific Institute of Artificial Limb-Fitting at Brussels, which was set up there in 1921 by the Permanent Inter-allied Committee for Disabled Men. The director of the International Labour Office, Mr. ALBERT THOMAS, who writes a prefatory note to the report, truly says that the International Labour Office would fail in its mission if it did not assert its direct value to those in many spheres who, in the words of the Peace Treaty, suffer from "injustice, hardship, and privation."

Dr. MARTIN's task was not a light one. To survey such a large field and to summarise the work done in Europe and America, giving due importance to each type of apparatus, without exaggeration of the merits of some or depreciation of the merits of others, is not easy; nor would it be difficult to find fault with some of the statements to which Dr. MARTIN has committed himself as to the usual practice in

Protoplasmic Action and Nervous Action.

By Ralph S. Lillie. Chicago, Illinois: University of Chicago Press. 1923. Pp. 417.

The volume is based on a series of lectures delivered to biologists. The author starts by complaining that far too much attention is being paid to analytical methods for studying organisms, whilst synthetic investigations on these lines are entirely neglected. Mr. Lillie claims that the problems involved in the transition between inanimate and animate systems are no more difficult than others which have yielded to scientific investigation; and that carefully planned investigations should go a long way towards solving the difficulties. Those who are under the influence of philosophies such as that of Herbert Spencer will have little sympathy for the author's views, and will be inclined to skip the 400 odd closely printed pages. This would be unfair, since, although one may hold the view that attempts to synthesise protoplasm are a waste of time, the actual experiments upon living tissues are worthy of consideration. Thus the chapters dealing with protoplasmic response to surface tension and chemical composition of the media are very good indeed. The concluding chapter contains a useful series of comparisons between conduction in nerve and various chemical reactions. Although the objects of the book are rather vague, the experimental details form interesting reading.

Masonry.

The Men's House. By J. Fort Newton. Pp. 261. *Symbolical Masonry.* By H. L. Haywood. Pp. 380. *The Great Teachings of Masonry.* By H. L. Haywood. Pp. 187. London: George Allen and Unwin, Ltd. 1924. 8s. 6d. each.

These three volumes, as their titles indicate, are written for Masons, whether they have only just become members of the craft or are well advanced in the higher degrees. But they are also of interest to the uninitiate, who will learn much about the aims of Masonry, and to a certain extent about the meaning of the Ritual. Dr. Newton's book consists of a series of papers upon various aspects of Masonry, including one on Rudyard Kipling, the Living Laureate of the Craft.

Of Mr. Haywood's two books "Symbolical Masonry" will be found most generally interesting, for symbolism and ritual appeal to every nation and class of men. The chapter on That Which Was Lost, deals with the Tetragrammaton—i.e., the ineffable Name of God. Shakespeare asked, "What's in a name?" but among primitive peoples there was a great deal in a name, for if anybody knew another's name he acquired some power over him. For instance, among primitive peoples it was almost a crime to address a fellow tribesman by his name, and instead of saying, "Old Cow, will you lend me a spear?" the would-be borrower, if he followed correct procedure, said, "Third cousin by the mother's side thrice removed, will you lend me a spear?" Among the ancient Hebrews the Name of God was regarded with such reverence that it was only allowed to be pronounced by one person on one day in the year—namely, by the High Priest on the Day of Atonement. And after the Temple was destroyed nobody ever said it at all. They *wrote* the tetragrammaton YHVH, but they *said* Adonai—i.e., the Lord—and no one knows to this day what the proper vowels for the tetragrammaton are. So the lost Name became a source of much mystical legend and teaching. Mr. Haywood's other volume deals with the teachings of Masonry and its aims and objects, and is good complement to the volume on Symbolism.

Messrs. Baillière, Tindall and Cox are the English agents for the "Annals of Medical History" of which Vol. VI., No. 1 was reviewed last week in this column. The annual subscription is £2 2s. per annum and the price of single copies is 12s. 6d.

EPSOM COLLEGE:

THE ANNUAL GENERAL MEETING.

At a well-attended annual general meeting of the Governors of Epsom College, held at 49, Bedford-square, W.C., on June 27th, Dr. Raymond Crawfurd in the chair, the annual report for the previous year recorded a good total of progress. Many certificates and distinctions were obtained, while of 31 boys who presented themselves for the War Office "Certificate A" 26 were successful. From the financial point of view the income and expenditure account for the year 1923 showed a substantial surplus of receipts over payments, this gratifying result being mainly due to the receipt of £4500 from the surviving trustees of the will of the Rev. J. W. W. Taylor, to a gift of £1000 by Mr. William Tinker, "to be administered as the Council think best," and to a further donation of £1000 from Lord Rosebery, earmarked for the addition to the College chapel. The rebuilding of the nave of the chapel in harmony with the new chancel was the object of the War Memorial Fund, and this fund remains open, while special efforts are being made by the Old Epsomian Club to collect the balance still required for the completion of the nave. Cheques towards the fund, drawn in favour of the Epsom College War Memorial Fund, should be sent to Mr. S. Maynard Smith, 49, Wimpole-street, W. 1; an announcement was made in the report that the supporters of the War Memorial Fund will be given the same voting privileges as those enjoyed by contributors to the Royal Medical Foundation of the College. The health of the boys was very good during the year reported upon.

In the forefront of the report was placed a record of the services of Sir Henry Morris, who has resigned the position of treasurer, being succeeded in this office by Mr. Herbert S. Pendlebury. After the secretary of the College had read Sir Henry Morris's formal resignation, the following resolution was moved from the chair and carried unanimously:—

> The Governors of Epsom College desire to record upon their minutes the deep regret with which they accept the resignation of the treasurership of the College by Sir Henry Morris, Bart., who for 18 years has carried out the onerous duties of that office with untiring zeal and energy. Only those who have been closely associated with him on the Council can realise the extent of the time and labour which he has devoted so disinterestedly to the service of the College, not only as treasurer, but also as chairman of the Works Committee, which additional office he has held for almost as long a period. In assuring Sir Henry Morris of their gratitude for all that he has done for the College, the Governors wish to endorse the expression of deep obligation which the Council has already conveyed to him, and they trust that he will live for many years to watch the continued progress of the College, and of the Royal Medical Foundation attached to it, in both of which he has been so keenly interested.

Beneficiaries under the Foundation.

The scrutineers, Dr. E. Climson Greenwood, Dr. Seymour Taylor, and Dr. Harold Spitta, then reported the successful candidates to be as under:—

ARTIFICIAL LIMBS.

A meeting of representatives of associations of disabled men of Austria, France, Germany, Great Britain, Italy, and Poland met at Geneva in 1921 and appealed to the International Labour Office to help to further the production of appliances for the benefit of the mutilated and to spread a knowledge of them. The office, which is connected with, but not a part of, the League of Nations, accordingly asked Dr. Florent Martin to compile a report which should set forth what has been done in all countries to provide prostheses and other appliances for the disabled with a view to helping not only sufferers in the late war, but also those whose injuries were received in civil life. Dr. Martin was well known during the war as the director of the artificial limb factory at La Panne, in Belgium, where, under his direction, was made an artificial leg, the merits of which he strongly advocated. He is now director of the Technical and Scientific Institute of Artificial Limb-Fitting at Brussels, which was set up there in 1921 by the Permanent Inter-allied Committee for Disabled Men. The director of the International Labour Office, Mr. Albert Thomas, who writes a prefatory note to the report, truly says that the International Labour Office would fail in its mission if it did not assert its direct value to those in many spheres who, in the words of the Peace Treaty, suffer from "injustice, hardship, and privation."

Dr. Martin's task was not a light one. To survey such a large field and to summarise the work done in Europe and America, giving due importance to each type of apparatus, without exaggeration of the merits of some or depreciation of the merits of others, is not easy; nor would it be difficult to find fault with some of the statements to which Dr. Martin has committed himself as to the usual practice in this country in prosthetic matters before the war and since 1914. He divides types of artificial limbs into two classes, American and European, but his descriptions of the European types are in many cases inapplicable to the limbs made in Great Britain. He is therefore not a very trustworthy guide here, and the British reader is more likely to profit by his survey of continental practice. The opinions expressed as to sites of amputations and the general principles of limb-fitting are sound, but we think that Dr. Martin is unduly pessimistic as regards certain end-bearing stumps. The light metal limb, which has become so popular in Britain, appears to be little known on the Continent, and its advantages and disadvantages not to be understood. The later results of cinematisation of stumps would appear to have been disappointing in France, Italy, and Belgium, as they have been here, where it may safely be said that the practice has been given up altogether. Information is lacking as to the true position of this procedure in Germany, where Sauerbruch continues to vaunt its success, but where most other surgeons are significantly silent on the subject. Neither is Krukenberg's procedure of splitting a forearm stump in order to form " tongs " recommended by Dr. Martin, whose references to German methods of limb-fitting are not copious. With his views on artificial hands we are in general agreement, though he is inclined to magnify their practical value. Appliances—the simpler the better—have proved of much greater practical worth than hands, though these have greater æsthetic value. His remarks about the problems arising from loss of both hands are suggestive, but he appears to be unacquainted with the ingenious table invented by Mr. George Thomson, of Edinburgh, which our Ministry of Pensions has supplied to handless men, and he reproduces 30 illustrations from a brochure by the English limb-maker, F. G. Ernst, on the equipment of such an amputee without mention of the author's name. This is not an isolated instance; although various American and other limb-makers are mentioned by name, none of the most successful British makers are named, although their work may be referred to.

We have nothing but praise for the public spirit and energy of the International Labour Office as shown in the production of this report, as well as in many other ways. It is to be feared, however, that interesting as it may be to surgeons and limb-makers, the British amputee will not gain much by a study of it.

◆

THE RELIEF OF ASTHENOPIA.

Binocular single vision depends upon the muscles of the two eyes being so coördinated that their combined action always maintains the parallelism of the two eyes. Its maintenance depends upon the reflex muscular response to the stimulation of light in the maculæ of the two eyes. When this stimulus is removed by the occlusion of one eye, the parallelism is still maintained, at any rate approximately, but in most cases only approximately. There is, as a rule, slight divergence, but there may be slight convergence or a slight vertical deviation from parallelism. The importance of slight lateral deviation is generally considered to be negligible so far as the necessity of treatment goes, but the occurrence of vertical deviation is found to be a not very uncommon cause of asthenopia which may call for treatment by appropriate prisms. This is the generally received view. Prof. F. W. Marlow,[1] in an essay recently published, goes far beyond this. He finds that by occluding one eye for a long period—say, a week—an amount of latent deviation, both lateral and vertical, is disclosed far in excess of what the ordinary Maddox rod test without any preliminary occlusion reveals. As is well known, latent errors of refraction can in many cases only be made evident after the paralysis of the ciliary muscle by means of atropine. Similarly, if we had a drug capable of paralysing the external muscles of the eye we might in that way discover the position of rest. As we have not, it is necessary to use the method of occlusion which attains the same object. According to Dr. A. Duane, such prolonged occlusion tends to make the eyes revert to their infantile state in which, not being controlled by coördinative influence, they exhibit a varying imbalance. Prof. Marlow disagrees and cites cases in which a week's occlusion has produced an exaggeration of the pre-existing heterophoria which does *not* vary. This position of rest, he says, affords relief to the strain on the extra-ocular muscles just as the correction of a refractive error may afford relief to an over-strained ciliary muscle, and according to him the prescription of appropriate prisms determined by the post-occlusion tests may relieve cases of asthenopia in which there may be no refractive error at all and in which the ordinary tests for heterophoria give negative results. The cases to which this method is applicable must necessarily be rare. The author, however, claims to have treated successfully cases of obscure asthenopia in which refraction and the muscle balance without occlusion were both normal, or in which the refractive error had already been corrected. The treatment advocated is the constant wearing of prisms where this is possible, and when not, operative treatment which, again, resolves itself into " partial tenotomy," an operation hitherto much more in vogue in America than in England.

◆

THE SCOTTISH BOARD OF HEALTH.

The fifth annual report of the Scottish Board of Health has just reached us. In a brief introduction it is noted that the general death-rate per 1000 of population reached the record figure of 12·9, and that the infantile mortality has dropped to 78·9 compared with 101·4 in 1922, a retrogressive year, and 90·3 in 1921. Even the present figure can hardly be regarded as satisfactory, though it shows considerable progress. The infantile mortality rates for England and Wales for the years 1922 and 1923 are 77 and 69·2 respectively. While climatic conditions are, on the whole, more favourable in England for rearing infants, it is acknowledged that the climate of every country generates its own methods of protection, and that special precautions in severer climates may, to a certain extent, counteract atmospheric conditions. In Norway and Sweden, for example, the infantile mortality is low. To the school health service is allotted more space than in former reports of the Board. Since out of 208,706 children examined during the school year, 100,980, or 48·3 per cent., were found to be suffering from physical defects, all must share the hope expressed in the report that the development of this service, curtailed by economic conditions, may soon be extended to its full capacity. The last section of the report includes a survey of the effects of unemployment on the physical welfare of the population, on the technical skill of trained and partly-trained workers, and on morale, which deserves careful study. The conclusion is reached that, thanks mainly to comprehensive relief measures, the period of serious unemployment which has now extended over three years, is not likely to leave a serious mark on the physique of the Scottish people. But there can be little doubt that young people growing up in a world that makes no call on their capacities for service are likely to suffer mentally and morally from such unstimulating conditions, and it is obvious that a revival of trade will result in the more energetic coöperation of young people in schemes designed for the improvement of the public health.

Annotations.

"Ne quid nimis."

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual report on the Museum of the Royal College of Surgeons by the Conservator, Sir Arthur Keith, opens with an appreciative account of the work done for the Museum by Prof. S. G. Shattock from his appointment as pathological curator in 1897, until his death on May 11th, 1924. Mr. Cecil F. Beadles, assistant curator, records donations made to the pathological series of specimens during the year, drawing special attention to a series of livers showing carcinoma associated with bilharzial cirrhosis, received from the South African Institute for Medical Research, Johannesburg (Dr. W. Watkins-Pitchford); shells of the fresh-water snails which form the intermediary host of *Schistosoma* in South Africa, from Mr. H. Temple Mursell, and of the Asiatic variety of the parasite in Japan from Dr. J. B. Christopherson; "radium carcinoma" of the thumb, removed from a man who had handled radium for many years, from Mr. C. P. G. Wakeley; and actinomycotic caries of foot in an ancient Egyptian, from Prof. D. Derry. The descriptive catalogue of the Army Medical Collection, which is in the custody of the Council of the College, makes good progress; the whole of Group A (gunshot injuries) has now been finally arranged and numbered. The Teratological Collection has been removed to a larger gallery and has received 14 additions during the year. The Collection of Surgical Instruments, to which Mr. Alban Doran continues to give devoted service, has been enriched by a set of thoracic callipers, goniometers, and three-plane stethometers described by the late Dr. Arthur Ransome in 1876; by the kymograph (or polygraph) used by Sir James Mackenzie before 1902; and by a number of ophthalmic instruments associated with the name of Sir John Tweedy and bequeathed by him to the College. In the physiological department, among other excellent work, Mr. Richard H. Burne, the curator, has supervised the histological examinations required by Sir Charles Ballance for experiments on the anastomoses of various nerves. Some early results of these experiments are recorded on p. 21 of this issue of THE LANCET. The Odontological Collection, of which Sir Frank Colyer is honorary director, and the Onodi Collection, under the supervision of Mr. T. B. Leyton, are being further extended. Research work is being actively pursued in all departments of the Museum and the usual courses of demonstrations were given by Sir Arthur Keith in association with the late Prof. S. G. Shattock in October, 1923, and with Mr. C. E. Shattock in March and April of this year. There remains for comment the report of the conservator on the department of human osteology, which is his own special province, and should also be a source of legitimate pride. The new catalogue being prepared by Miss M. L. Tildesley, appointed research assistant for this purpose in 1920, is only now approaching completion, since the work has been much more complicated than was estimated. It is to be hoped that it will be possible to retain Miss Tildesley's services until the work is accomplished. During the past year—through the generosity of the town council of Scarborough—an important addition was made to this collection. In the course of certain excavations the graves of men, women, and children, representatives of the population of the East Riding between the eleventh and sixteenth centuries, had to be disturbed and the remains of 130 individuals were handed over to the Royal College of Surgeons for preservation and study. Sir Arthur Keith answers the question often put to him by casual visitors to the Museum—What is the use of making such an assemblage of human skulls and skeletons? The main object is the study of man—the anatomy of his body in present and past times. His skeleton is the only permanent part of his body—it is by the study of skeletal remains, often of a fragmentary nature, that the anatomist or anthropologist has to unravel the history of man's body and trace the evolution of its various parts and identify racial migrations. The only means of telling how far man's body can withstand the conditions set up by modern civilisation is by the comparison of the same people at different epochs. This can be done only by a study of skeletal remains. The department of human osteology in the Museum is not a thing of recent creation; its foundation was laid by Hunter. The foresight of a long line of conservators—of whom not the least zealous is the present holder of that office—has made it the standard collection of its kind for the British Empire.

THE TREATMENT OF INFECTED TEETH.

IT is common knowledge that a considerable number of pulpless teeth, including many that have received dental treatment, may show areas of rarefaction of bone around the ends of the roots as revealed by radiographic examination, the lesions constituting one of the forms of dental sepsis. The modern tendency is to regard these infected areas as representing a more potentially dangerous form of focal infection than the more open lesions of pyorrhœa. The view has often been expressed that all such teeth should be removed, especially when there is reason to suspect that they may be related to some general disturbance of health. This is counsel which would put an end to a large field of conservative dentistry. These teeth are usually free from local symptoms; they are often firmly implanted and are serviceable aids to mastication. The usual method of treatment by mechanically removing infected debris from the root canals and introducing various antiseptics has the disadvantage that the chief infection is outside the tooth in the bone around the apex. Since the root canal progressively narrows towards the apex, the possibility of an antiseptic acting on the peri-apical tissues seems slight. Over two years ago H. C. Moxham [1] suggested a method of treating infected teeth by introducing an emulsion of *Bacillus bulgaricus* into the canals. He showed by laboratory experiments on freshly extracted teeth that if the canals were rendered sterile and then inoculated with streptococci or staphylococci, these organisms were killed in 24 hours by *B. bulgaricus* introduced into the canals. He followed up this work by treating infected teeth in the mouth in the same way. The root canals were mechanically cleansed and milk cultures of *B. bulgaricus* placed in the canals and sealed in for periods varying from one day to three weeks. The canals were then opened under aseptic precautions. A decided smell of lactic acid was noticed in some cases. A bacteriological test was made and it was found in most cases that living *B. bulgaricus* was the only organism present in the canals, the others having been killed. Of 25 teeth with fistulæ present 22 responded to the treatment, as shown by the rapid healing of the sinus, and no discomfort was suffered by the patient. The only way of determining whether this method of treatment can affect the diseased areas outside the tooth is by radiographic examination at intervals to ascertain whether the rarefied areas show signs of diminishing and becoming denser; a test not free from fallacies. The results, according to Moxham, are encouraging, though not conclusive. This work did not attract much attention, but recently F. C. Wilkinson [2] has published a paper describing his results, using the same technique as Moxham. He finds with the latter that the clinical results are good and that the *B. bulgaricus* effectively replaces the other organisms present in infected canals. The radiographic results are less encouraging. In one case the films appeared to show definite

evidence of osseous regeneration; in some others there was slight evidence of improvement, while the rest were doubtful or negative. The number of teeth treated was only eight; this is explained by the difficulty of obtaining bacteriological coöperation. The radiographic test is certainly not very satisfactory, for to compare films of the same tooth taken at intervals and to interpret any differences as valid evidence of anatomical change is to leave out of account various factors concerned with radiographic technique which may easily vitiate the results. A better method which might be possible in a few cases would be to select teeth showing apical rarefaction and to treat them with cultures of *B. bulgaricus* and then to trephine the bone and examine the peri-apical tissues bacteriologically, but it might not be easy to find patients willing to submit to the test even in the cause of science. The results of both Moxham and Wilkinson are sufficiently hopeful to deserve further investigation. The careful coöperation required between dentist, radiologist, and bacteriologist makes it essentially a study to be carried out in a dental hospital. The pulpless tooth forms one of the most important problems in modern dentistry to-day, and any method which might promise a solution compatible with the retention of these teeth in a healthy condition is worth investigating on an extensive scale.

MIDWIVES AND JURY SERVICE.

The Home Secretary, having been approached by the Ministry of Health with regard to the liability of women working as midwives to serve on juries, has sent a circular letter on the subject to the under-sheriffs. It is pointed out that the question of legislation to secure general exemption for all midwives in virtue of their calling will be considered when a suitable opportunity presents itself. The circular contains sympathetic reference to the undoubted need of midwives for special consideration in view of the necessary urgency of calls upon them for their attendance at confinements. Further, the Home Secretary expresses the view that in practice midwives are excused from service when their aid is urgently required, and suggests that upon under-sheriffs being satisfied that a certified midwife has given notice to a local supervising authority of her intention to practise as such, a mark should be placed against her name in the jury book so as to prevent a summons being sent to her. If the terms of this instruction or suggestion are complied with, it seems that midwives will have no further ground for complaint. By a schedule to the Juries Act, 1870, a large number of classes of persons are exempted from jury service, including peers, Members of Parliament, judges, clergymen, and ministers of religion as defined by the schedule, barristers, solicitors, and various other persons engaged in the practice of the law. All registered medical practitioners and pharmaceutical chemists are also exempt, as well as officers of the navy, army, and other services, civil and otherwise, including police officers and justices of the peace.

SPLANCHNIC ANÆSTHESIA.

In a visit to a continental surgical clinic nothing is more likely to strike an observer than the contrast of the methods of anæsthesia there adopted with those prevalent in our own operating theatres. On the Continent a reliance is commonly placed on methods of local and regional anæsthesia, whilst the skilled technique of general anæsthesia to which we are accustomed does not seem to have been developed. Yet the very skill of our own anæsthetists has largely blinded us to the undoubted advantages of local methods. As Crile pointed out, the protection of the subconscious centres is of vital importance and can only be effectively carried out by a local nerve-block. The method of splanchnic anæsthesia has been extensively used on the Continent, and the article which we publish this week, by Mr. Stanley Hillman, gives examples of its remarkable possibilities. The technique of the method is simple, though it requires accuracy of execution, and the resulting block is so complete that even the largest operations can be carried out without pain and with an absence of shock unapproached in other methods. The method consists in the injection of about 50 c.cm. of 1 per cent. novocaine into the region of the semilunar ganglia, a very fine needle being inserted on either side of the first lumbar vertebra for the purpose. A preliminary aspiration ensures that a vessel has not been entered. Not only can extensive operations on the stomach be then conducted without pain or shock, but this inhibition may persist for long after the operation is concluded and well into the period of convalescence. Brunn and Mandl in the *Wiener klinische Wochenschrift* of May 22nd, 1924, describe another remarkable use of this inhibition of the sympathetic nerves. Injecting at different levels in the dorsal region so as to block the rami communicantes of the sympathetic ganglia, they have succeeded in cutting out afferent impulses from various organs, such as the gall-bladder and kidney. They suggest the use of the method as a means of differential diagnosis between lesions of the different viscera, but they also consider that the injections may in certain circumstances have an actual curative effect. The cutting of the reflex which results relieves spasm of the musculature of the viscus, and the cases they describe suggest that under these circumstances a gall-stone may be passed or a kidney recover its inhibited function. The method appears to open up a new field and its development will be followed with interest.

MOSQUITO CONTROL AT HAYLING ISLAND.

A piece of interesting and useful health work about which too little is known has for several years been carried out at Hayling Island in Hants. It is concerned with the amelioration of the mosquito pest in the neighbourhood and owes its origin and much of its success to the enthusiasm and efforts of Mr. J. F. Marshall, F.E.S. He and the members of the executive committee of the Mosquito Control association have issued a third report which gives an account of the work accomplished from May, 1923, to May, 1924. It is a well-illustrated pamphlet of 12 pages which, after certain remarks on mosquitoes generally and the methods employed for their reduction, considers in some detail the objects of the Hayling Mosquito Control. This was organised in 1920 to cope with the intolerable mosquito nuisance so prevalent at a large number of summer resorts along the coast-line of Dorset, Hampshire, Sussex, and Kent. A laboratory was established at Hayling Island and investigations showed that the chief mosquito culprit was *Ochlerotatus detritus*, a salt-marsh breeder. Aided by *Ochlerotatus rusticus*, the larvæ of which are found in the stagnant fresh water of field and roadside ditches, and by *Theobaldia annulata*, whose larvæ have a liking for foul waters contaminated by sewage or other refuse, this mosquito does its best to make life miserable by its blood-sucking propensities. It has a greater range of flight than either of its two "non-salt" congeners, but the latter are often a cause of serious annoyance, and the Hayling Mosquito Control plead for the assistance of local sanitary authorities and of landowners not only against these insects, but with respect to *Culex pipiens*, the common "domestic" gnat which, though probably less blood-thirsty than the other species, yet merits attention. The intensive work of the Control against *Ochlerotatus detritus* is indicated by an excellent map of the "Salterns" area of Hayling Island, and it is gratifying to find how much has been accomplished in the way of abolishing mosquito nurseries. White Cross disinfectant in a strength of 1 part in 30,000 has been found useful as a larvicide, and water thus treated is harmless if drunk by human beings or animals. A good deal of drainage has been carried out, and it is noteworthy that the Control has received monetary support for its operations from the Ministry of Health

on the recommendation of Colonel S. P. James. The grant has been suitably bestowed for, despite considerable difficulties, marked improvements have been effected. Reference is made to the somewhat similar work carried out on behalf of the Navy by Surg.-Commander D. H. C. Given, R.N., in the Gosport and Alverstoke district, where formerly the residents were unable to sit out in their gardens of an evening owing to the attacks of mosquitoes. The use of larvivorous shrimps, which was a feature of the naval operations, is not mentioned. The report concludes with a list of the known British mosquitoes and a description of the four species with which the Hayling Mosquito Control is specially concerned. An informative museum has been established at Seacourt, South Hayling, the residence of Mr. Marshall, and is open to the public, while lectures and lantern demonstrations are given at stated times. This report records with commendable brevity and modesty work which merits recognition.

DENTAL JURISPRUDENCE.

IN a paper on the Dentist and the State, read by Mr. H. Cantor at the annual business meeting of the London Hospital Dental Society, interesting reference was made to the evidence of identity which may be obtained from the teeth of a deceased person. Cases will occur to all in which human remains have been found where the circumstances accompanying or following death have made impossible recognition by persons familiar with the appearance of the deceased when alive, or have rendered errors of identification easy. In cases of death by drowning, or where the body has lain for long exposed or long buried before discovery, the teeth may be the one distinctive and unchanged feature that survives. A murderer often makes an attempt to destroy deliberately all evidence of the identity of his victim, but even the use of fire for this purpose is apt to leave fragments which an expert can recognise who has had the mouth of the deceased under his care. Mr. Cantor gave as examples the identification of the mutilated remains of the Prince Imperial during the Zulu War through a gold filling, and of the remains of the Duchesse d'Alençon after the fire at the Bazar de la Charité in Paris, by a denture which fitted the plaster cast retained by her dentist. It is not necessary to labour the matter. The dentist clearly can supply evidence practically beyond contradiction as to the identity of human remains, if the jaws, or a reasonable portion of their dental equipment, have been preserved, if there is some clue as to the identity which needs authoritative confirmation or disproof, and if the dentist applied to has kept careful records. The limitations of this method of identification are obvious; a large class of persons do not have recourse to dentists, or at any rate do not have accurate records made of their dental conditions.

THE TREATMENT OF VENEREAL ADENITIS BY SOLAR RAYS.

THE salutary effects of the sun are commonplace knowledge in these days as they were in ancient times, when even the caves which served as dwelling places were chosen where they faced the south. Among the Romans exposure to sunlight was held to be not only a remedy but a valuable hygienic measure, and Hippocrates, Celsus, and Galen prescribed sun-baths in certain diseases. At the present day the practical application of this remedial agent has been vastly extended, and good results have been obtained in a large sphere of diseases, such as tuberculosis, leukæmia, Basedow's disease, epithelioma and dermato-syphilis. Dr. Gino Murero, of the dermato-syphilitic clinic at Bologna, publishes[1] five cases of suppurative inguinal adenitis from venereal ulcers, which tend to show that distinct beneficial effects can be obtained in intractable cases by exposure to solar rays. His technique is to choose the morning hours for the exposure, especially in the months of July and August, when the temperature is less high than during the rest of the day, thus avoiding disturbances and profuse sweating caused by excessive heat, and also because in the morning hours the atmosphere is clearer and does not absorb so many ultra-violet rays. The diseased part is exposed directly to the sun while the patient lies on a bench, the rest of the body being suitably protected by coloured curtains. The only application used was sterilised gauze. In all the five cases improvement took place almost at once after four or five sittings, but the healing process increased about the ninth or tenth exposure with the disappearance of the œdema and of the bluish-red tint of the edges, and with the elimination of the necrotic patches, which are usually seen at the base of the ulcer, and their replacement by healthy granulations and consequent transformation and diminution of sanious discharge. Cure was usually complete after 25 sittings. It is worth while drawing attention to these results, because such abscesses as sequelæ of ulcers, due to Ducrey's bacillus, by their resistance to ordinary methods of cure, are the cause of much physical suffering and expense to the patient. No special technique is needed, nor is any exclusive locality absolutely indispensable for the treatment; the patient can obtain the cure of his disease wherever there is possibility of exposing the affected parts of the body to the sun's rays. Medical observation and control, it need hardly be said, are absolutely necessary if uneventful cure is to be assured.

THE PREVENTION OF AEROPLANE CRASHES.

THE aviation display at Hendon last Saturday passed off without mishap. The mechanical efficiency of modern planes will be given the chief credit for this gratifying circumstance; but according to the figures set out in a well-reasoned contribution to the U.S. Naval Medical Bulletin for March, praise should be offered rather to the qualities of quick judgment and resolute decision possessed by the British and French aviators who took part. Under the title of "Aviation Accidents and Methods of Prevention" Lieutenant J. F. Neuberger, Medical Corps, U.S. Navy, who has been serving in the flagship of the Aircraft Squadrons Scouting Fleet, discusses the lessons to be learnt from the statistics collected. The causes of investigated crashes in the experience of the U.S. Navy in 1922 were physical and mental defect, 60 per cent.; insufficient knowledge and experience, 10 per cent.; mechanical (plane or motor), 24 per cent.; weather, 4 per cent.; unavoidable, 2 per cent. The chief cause of crashes is thus some mental defect, including error of judgment, in the aviator himself. It is pointed out that slowness of reaction time should be recognised during the medical examination of the candidate for the Air Force; the slow-reacting man might just as well be disqualified then, or when undergoing recruit training, as later. At this stage he will not have killed anyone or caused loss to the public by damaging expensive machinery. Most men learn to fly in eight hours; why trouble to accept those who cannot learn under 10? Medical officers of aviation units should be officers who themselves fly, are keen on flying, and understand the aviators' difficulties. A flight surgeon should be told off to go through the recruit's course with each batch under instruction, that he may know the individuals intimately, and be able to estimate their flying ability with full understanding. Medical observation should not cease when they are graded pilots, but should be continuous until they fly. The U.S. Navy uses the Schneider test, which relies on blood pressure variation lying and standing, and on the effect of exertion on the pulse-rate. It is noteworthy that at a great flying school 66 per cent. of the accidents happened on Mondays or on days after holidays. Lieut. Neuberger urges that the medical officer should not be regarded by the aviator as an

evidence of osseous regeneration; in some others there was slight evidence of improvement, while the rest were doubtful or negative. The number of teeth treated was only eight; this is explained by the difficulty of obtaining bacteriological coöperation. The radiographic test is certainly not very satisfactory, for to compare films of the same tooth taken at intervals and to interpret any differences as valid evidence of anatomical change is to leave out of account various factors concerned with radiographic technique which may easily vitiate the results. A better method which might be possible in a few cases would be to select teeth showing apical rarefaction and to treat them with cultures of *B. bulgaricus* and then to trephine the bone and examine the peri-apical tissues bacteriologically, but it might not be easy to find patients willing to submit to the test even in the cause of science. The results of both Moxham and Wilkinson are sufficiently hopeful to deserve further investigation. The careful coöperation required between dentist, radiologist, and bacteriologist makes it essentially a study to be carried out in a dental hospital. The pulpless tooth forms one of the most important problems in modern dentistry to-day, and any method which might promise a solution compatible with the retention of these teeth in a healthy condition is worth investigating on an extensive scale.

MIDWIVES AND JURY SERVICE.

The Home Secretary, having been approached by the Ministry of Health with regard to the liability of women working as midwives to serve on juries, has sent a circular letter on the subject to the under-sheriffs. It is pointed out that the question of legislation to secure general exemption for all midwives in virtue of their calling will be considered when a suitable opportunity presents itself. The circular contains sympathetic reference to the undoubted need of midwives for special consideration in view of the necessary urgency of calls upon them for their attendance at confinements. Further, the Home Secretary expresses the view that in practice midwives are excused from service when their aid is urgently required, and suggests that upon under-sheriffs being satisfied that a certified midwife has given notice to a local supervising authority of her intention to practise as such, a mark should be placed against her name in the jury book so as to prevent a summons being sent to her. If the terms of this instruction or suggestion are complied with, it seems that midwives will have no further ground for complaint. By a schedule to the Juries Act, 1870, a large number of classes of persons are exempted from jury service, including peers, Members of Parliament, judges, clergymen, and ministers of religion as defined by the schedule, barristers, solicitors, and various other persons engaged in the practice of the law. All registered medical practitioners and pharmaceutical chemists are also exempt, as well as officers of the navy, army, and other services, civil and otherwise, including police officers and justices of the peace.

SPLANCHNIC ANÆSTHESIA.

In a visit to a continental surgical clinic nothing is more likely to strike an observer than the contrast of the methods of anæsthesia there adopted with those prevalent in our own operating theatres. On the Continent a reliance is commonly placed on methods of local and regional anæsthesia, whilst the skilled technique of general anæsthesia to which we are accustomed does not seem to have been developed. Yet the very skill of our own anæsthetists has largely blinded us to the undoubted advantages of local methods. As Crile pointed out, the protection of the subconscious centres is of vital importance and can only be effectively carried out by a local nerve-block. The method of splanchnic anæsthesia has been extensively used on the Continent, and the article which we publish this week, by Mr. Stanley Hillman, gives examples of its remarkable possibilities. The technique of the method is simple, though it requires accuracy of execution, and the resulting block is so complete that even the largest operations can be carried out without pain and with an absence of shock unapproached in other methods. The method consists in the injection of about 50 c.cm. of 1 per cent. novocaine into the region of the semilunar ganglia, a very fine needle being inserted on either side of the first lumbar vertebra for the purpose. A preliminary aspiration ensures that a vessel has not been entered. Not only can extensive operations on the stomach be then conducted without pain or shock, but this inhibition may persist for long after the operation is concluded and well into the period of convalescence. Brunn and Mandl in the *Wiener klinische Wochenschrift* of May 22nd, 1924, describe another remarkable use of this inhibition of the sympathetic nerves. Injecting at different levels in the dorsal region so as to block the rami communicantes of the sympathetic ganglia, they have succeeded in cutting out afferent impulses from various organs, such as the gall-bladder and kidney. They suggest the use of the method as a means of differential diagnosis between lesions of the different viscera, but they also consider that the injections may in certain circumstances have an actual curative effect. The cutting of the reflex which results relieves spasm of the musculature of the viscus, and the cases they describe suggest that under these circumstances a gall-stone may be passed or a kidney recover its inhibited function. The method appears to open up a new field and its development will be followed with interest.

MOSQUITO CONTROL AT HAYLING ISLAND.

A piece of interesting and useful health work about which too little is known has for several years been carried out at Hayling Island in Hants. It is concerned with the amelioration of the mosquito pest in the neighbourhood and owes its origin and much of its success to the enthusiasm and efforts of Mr. J. F. Marshall, F.E.S. He and the members of the executive committee of the Mosquito Control association have issued a third report which gives an account of the work accomplished from May, 1923, to May, 1924. It is a well-illustrated pamphlet of 12 pages which, after certain remarks on mosquitoes generally and the methods employed for their reduction, considers in some detail the objects of the Hayling Mosquito Control. This was organised in 1920 to cope with the intolerable mosquito nuisance so prevalent at a large number of summer resorts along the coast-line of Dorset, Hampshire, Sussex, and Kent. A laboratory was established at Hayling Island and investigations showed that the chief mosquito culprit was *Ochlerotatus detritus*, a salt-marsh breeder. Aided by *Ochlerotatus rusticus*, the larvæ of which are found in the stagnant fresh water of field and roadside ditches, and by *Theobaldia annulata*, whose larvæ have a liking for foul waters contaminated by sewage or other refuse, this mosquito does its best to make life miserable by its blood-sucking propensities. It has a greater range of flight than either of its two "non-salt" congeners, but the latter are often a cause of serious annoyance, and the Hayling Mosquito Control plead for the assistance of local sanitary authorities and of landowners not only against these insects, but with respect to *Culex pipiens*, the common "domestic" gnat which, though probably less blood-thirsty than the other species, yet merits attention. The intensive work of the Control against *Ochlerotatus detritus* is indicated by an excellent map of the "Salterns" area of Hayling Island, and it is gratifying to find how much has been accomplished in the way of abolishing mosquito nurseries. White Cross disinfectant in a strength of 1 part in 30,000 has been found useful as a larvicide, and water thus treated is harmless if drunk by human beings or animals. A good deal of drainage has been carried out, and it is noteworthy that the Control has received monetary support for its operations from the Ministry of Health

on the recommendation of Colonel S. P. James. The grant has been suitably bestowed for, despite considerable difficulties, marked improvements have been effected. Reference is made to the somewhat similar work carried out on behalf of the Navy by Surg.-Commander D. H. C. Given, R.N., in the Gosport and Alverstoke district, where formerly the residents were unable to sit out in their gardens of an evening owing to the attacks of mosquitoes. The use of larvivorous shrimps, which was a feature of the naval operations, is not mentioned. The report concludes with a list of the known British mosquitoes and a description of the four species with which the Hayling Mosquito Control is specially concerned. An informative museum has been established at Seacourt, South Hayling, the residence of Mr. Marshall, and is open to the public, while lectures and lantern demonstrations are given at stated times. This report records with commendable brevity and modesty work which merits recognition.

DENTAL JURISPRUDENCE.

IN a paper on the Dentist and the State, read by Mr. H. Cantor at the annual business meeting of the London Hospital Dental Society, interesting reference was made to the evidence of identity which may be obtained from the teeth of a deceased person. Cases will occur to all in which human remains have been found where the circumstances accompanying or following death have made impossible recognition by persons familiar with the appearance of the deceased when alive, or have rendered errors of identification easy. In cases of death by drowning, or where the body has lain for long exposed or long buried before discovery, the teeth may be the one distinctive and unchanged feature that survives. A murderer often makes an attempt to destroy deliberately all evidence of the identity of his victim, but even the use of fire for this purpose is apt to leave fragments which an expert can recognise who has had the mouth of the deceased under his care. Mr. Cantor gave as examples the identification of the mutilated remains of the Prince Imperial during the Zulu War through a gold filling, and of the remains of the Duchesse d'Alençon after the fire at the Bazar de la Charité in Paris, by a denture which fitted the plaster cast retained by her dentist. It is not necessary to labour the matter. The dentist clearly can supply evidence practically beyond contradiction as to the identity of human remains, if the jaws, or a reasonable portion of their dental equipment, have been preserved, if there is some clue as to the identity which needs authoritative confirmation or disproof, and if the dentist applied to has kept careful records. The limitations of this method of identification are obvious; a large class of persons do not have recourse to dentists, or at any rate do not have accurate records made of their dental conditions.

THE TREATMENT OF VENEREAL ADENITIS BY SOLAR RAYS.

THE salutary effects of the sun are commonplace knowledge in these days as they were in ancient times, when even the caves which served as dwelling places were chosen where they faced the south. Among the Romans exposure to sunlight was held to be not only a remedy but a valuable hygienic measure, and Hippocrates, Celsus, and Galen prescribed sun-baths in certain diseases. At the present day the practical application of this remedial agent has been vastly extended, and good results have been obtained in a large sphere of diseases, such as tuberculosis, leukæmia, Basedow's disease, epithelioma and dermato-syphilis. Dr. Gino Murero, of the dermato-syphilitic clinic at Bologna, publishes[1] five cases of suppurative inguinal adenitis from venereal ulcers, which tend to show that distinct beneficial effects can be obtained in intractable cases by exposure to solar rays. His technique is to choose the morning hours for the exposure, especially in the months of July and August, when the temperature is less high than during the rest of the day, thus avoiding disturbances and profuse sweating caused by excessive heat, and also because in the morning hours the atmosphere is clearer and does not absorb so many ultra-violet rays. The diseased part is exposed directly to the sun while the patient lies on a bench, the rest of the body being suitably protected by coloured curtains. The only application used was sterilised gauze. In all the five cases improvement took place almost at once after four or five sittings, but the healing process increased about the ninth or tenth exposure with the disappearance of the œdema and of the bluish-red tint of the edges, and with the elimination of the necrotic patches, which are usually seen at the base of the ulcer, and their replacement by healthy granulations and consequent transformation and diminution of sanious discharge. Cure was usually complete after 25 sittings. It is worth while drawing attention to these results, because such abscesses as sequelæ of ulcers, due to Ducrey's bacillus, by their resistance to ordinary methods of cure, are the cause of much physical suffering and expense to the patient. No special technique is needed, nor is any exclusive locality absolutely indispensable for the treatment; the patient can obtain the cure of his disease wherever there is possibility of exposing the affected parts of the body to the sun's rays. Medical observation and control, it need hardly be said, are absolutely necessary if uneventful cure is to be assured.

THE PREVENTION OF AEROPLANE CRASHES.

THE aviation display at Hendon last Saturday passed off without mishap. The mechanical efficiency of modern planes will be given the chief credit for this gratifying circumstance; but according to the figures set out in a well-reasoned contribution to the U.S. Naval Medical Bulletin for March, praise should be offered rather to the qualities of quick judgment and resolute decision possessed by the British and French aviators who took part. Under the title of "Aviation Accidents and Methods of Prevention" Lieutenant J. F. Neuberger, Medical Corps, U.S. Navy, who has been serving in the flagship of the Aircraft Squadrons Scouting Fleet, discusses the lessons to be learnt from the statistics collected. The causes of investigated crashes in the experience of the U.S. Navy in 1922 were physical and mental defect, 60 per cent.; insufficient knowledge and experience, 10 per cent.; mechanical (plane or motor), 24 per cent.; weather, 4 per cent.; unavoidable, 2 per cent. The chief cause of crashes is thus some mental defect, including error of judgment, in the aviator himself. It is pointed out that slowness of reaction time should be recognised during the medical examination of the candidate for the Air Force; the slow-reacting man might just as well be disqualified then, or when undergoing recruit training, as later. At this stage he will not have killed anyone or caused loss to the public by damaging expensive machinery. Most men learn to fly in eight hours; why trouble to accept those who cannot learn under 10? Medical officers of aviation units should be officers who themselves fly, are keen on flying, and understand the aviators' difficulties. A flight surgeon should be told off to go through the recruit's course with each batch under instruction, that he may know the individuals intimately, and be able to estimate their flying ability with full understanding. Medical observation should not cease when they are graded pilots, but should be continuous until they fly. The U.S. Navy uses the Schneider test, which relies on blood pressure variation lying and standing, and on the effect of exertion on the pulse-rate. It is noteworthy that at a great flying school 66 per cent. of the accidents happened on Mondays or on days after holidays. Lieut. Neuberger urges that the medical officer should not be regarded by the aviator as an

evidence of osseous regeneration; in some others there was slight evidence of improvement, while the rest were doubtful or negative. The number of teeth treated was only eight; this is explained by the difficulty of obtaining bacteriological coöperation. The radiographic test is certainly not very satisfactory, for to compare films of the same tooth taken at intervals and to interpret any differences as valid evidence of anatomical change is to leave out of account various factors concerned with radiographic technique which may easily vitiate the results. A better method which might be possible in a few cases would be to select teeth showing apical rarefaction and to treat them with cultures of *B. bulgaricus* and then to trephine the bone and examine the peri-apical tissues bacteriologically, but it might not be easy to find patients willing to submit to the test even in the cause of science. The results of both Moxham and Wilkinson are sufficiently hopeful to deserve further investigation. The careful coöperation required between dentist, radiologist, and bacteriologist makes it essentially a study to be carried out in a dental hospital. The pulpless tooth forms one of the most important problems in modern dentistry to-day, and any method which might promise a solution compatible with the retention of these teeth in a healthy condition is worth investigating on an extensive scale.

---

[1] La Riforma Medica, June 2nd, 1924.

MIDWIVES AND JURY SERVICE.

THE Home Secretary, having been approached by the Ministry of Health with regard to the liability of women working as midwives to serve on juries, has sent a circular letter on the subject to the under-sheriffs. It is pointed out that the question of legislation to secure general exemption for all midwives in virtue of their calling will be considered when a suitable opportunity presents itself. The circular contains sympathetic reference to the undoubted need of midwives for special consideration in view of the necessary urgency of calls upon them for their attendance at confinements. Further, the Home Secretary expresses the view that in practice midwives are excused from service when their aid is urgently required, and suggests that upon under-sheriffs being satisfied that a certified midwife has given notice to a local supervising authority of her intention to practise as such, a mark should be placed against her name in the jury book so as to prevent a summons being sent to her. If the terms of this instruction or suggestion are complied with, it seems that midwives will have no further ground for complaint. By a schedule to the Juries Act, 1870, a large number of classes of persons are exempted from jury service, including peers, Members of Parliament, judges, clergymen, and ministers of religion as defined by the schedule, barristers, solicitors, and various other persons engaged in the practice of the law. All registered medical practitioners and pharmaceutical chemists are also exempt, as well as officers of the navy, army, and other services, civil and otherwise, including police officers and justices of the peace.

SPLANCHNIC ANÆSTHESIA.

IN a visit to a continental surgical clinic nothing is more likely to strike an observer than the contrast of the methods of anæsthesia there adopted with those prevalent in our own operating theatres. On the Continent a reliance is commonly placed on methods of local and regional anæsthesia, whilst the skilled technique of general anæsthesia to which we are accustomed does not seem to have been developed. Yet the very skill of our own anæsthetists has largely blinded us to the undoubted advantages of local methods. As Crile pointed out, the protection of the subconscious centres is of vital importance and can only be effectively carried out by a local nerve-block. The method of splanchnic anæsthesia has been extensively used on the Continent, and the article which we publish this week, by Mr. Stanley Hillman, gives examples of its remarkable possibilities. The technique of the method is simple, though it requires accuracy of execution, and the resulting block is so complete that even the largest operations can be carried out without pain and with an absence of shock unapproached in other methods. The method consists in the injection of about 50 c.cm. of 1 per cent. novocaine into the region of the semilunar ganglia, a very fine needle being inserted on either side of the first lumbar vertebra for the purpose. A preliminary aspiration ensures that a vessel has not been entered. Not only can extensive operations on the stomach be then conducted without pain or shock, but this inhibition may persist for long after the operation is concluded and well into the period of convalescence. Brunn and Mandl in the *Wiener klinische Wochenschrift* of May 22nd, 1924, describe another remarkable use of this inhibition of the sympathetic nerves. Injecting at different levels in the dorsal region so as to block the rami communicantes of the sympathetic ganglia, they have succeeded in cutting out afferent impulses from various organs, such as the gall-bladder and kidney. They suggest the use of the method as a means of differential diagnosis between lesions of the different viscera, but they also consider that the injections may in certain circumstances have an actual curative effect. The cutting of the reflex which results relieves spasm of the musculature of the viscus, and the cases they describe suggest that under these circumstances a gall-stone may be passed or a kidney recover its inhibited function. The method appears to open up a new field and its development will be followed with interest.

MOSQUITO CONTROL AT HAYLING ISLAND.

A PIECE of interesting and useful health work about which too little is known has for several years been carried out at Hayling Island in Hants. It is concerned with the amelioration of the mosquito pest in the neighbourhood and owes its origin and much of its success to the enthusiasm and efforts of Mr. J. F. Marshall, F.E.S. He and the members of the executive committee of the Mosquito Control association have issued a third report which gives an account of the work accomplished from May, 1923, to May, 1924. It is a well-illustrated pamphlet of 12 pages which, after certain remarks on mosquitoes generally and the methods employed for their reduction, considers in some detail the objects of the Hayling Mosquito Control. This was organised in 1920 to cope with the intolerable mosquito nuisance so prevalent at a large number of summer resorts along the coast-line of Dorset, Hampshire, Sussex, and Kent. A laboratory was established at Hayling Island and investigations showed that the chief mosquito culprit was *Ochlerotatus detritus*, a salt-marsh breeder. Aided by *Ochlerotatus rusticus*, the larvæ of which are found in the stagnant fresh water of field and roadside ditches, and by *Theobaldia annulata*, whose larvæ have a liking for foul waters contaminated by sewage or other refuse, this mosquito does its best to make life miserable by its blood-sucking propensities. It has a greater range of flight than either of its two "non-salt" congeners, but the latter are often a cause of serious annoyance, and the Hayling Mosquito Control plead for the assistance of local sanitary authorities and of landowners not only against these insects, but with respect to *Culex pipiens*, the common "domestic" gnat which, though probably less blood-thirsty than the other species, yet merits attention. The intensive work of the Control against *Ochlerotatus detritus* is indicated by an excellent map of the "Salterns" area of Hayling Island, and it is gratifying to find how much has been accomplished in the way of abolishing mosquito nurseries. White Cross disinfectant in a strength of 1 part in 30,000 has been found useful as a larvicide, and water thus treated is harmless if drunk by human beings or animals. A good deal of drainage has been carried out, and it is noteworthy that the Control has received monetary support for its operations from the Ministry of Health

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXVIII.

TREATMENT OF THE COMMONER AFFECTIONS OF THE SCALP.

Scurfiness.

IT is not proposed here to say anything about localised patches of scurfiness due to specific conditions such as ringworm, psoriasis, &c., but to deal only with those conditions which are usually included under the term pityriasis of the scalp. Two forms are recognised: a dry form (pityriasis simplex), and a moist or greasy form (pityriasis steatoides). In the former there is a simple hyperkeratosis of the scalp with desquamation, while in the latter some inflammatory exudate of serum has taken place among the scales, thus altering their character. There is, however, no hard-and-fast dividing line between the two conditions.

Pityriasis Simplex.—Pityriasis simplex may occur in children, not infrequently in infants, in whom it often first makes its appearance in the form of rings. It is, however, chiefly seen in adults, particularly in men. It is generally due to bacterial infection, the infecting agent being probably the bottle bacillus, but in some cases it is due simply to a deficiency in the normal oil secreted by the skin glands, as, for example, in xerodermia. A differentiation between the two types is not always easy, but the general dryness of the rest of the skin and hair should favour a diagnosis of the latter type. Microscopic examination of the scales is helpful but not conclusive, as the bottle bacillus is a normal saprophyte of the scalp.

Treatment will vary in the two conditions. It is obvious that if the skin is too dry repeated washings are not likely to help, whereas if a bacterial infection is present these may be of considerable value. In the former case, therefore, in boys and men, it is best to confine washing of the scalp to once a week, and to give some slightly oily preparation to replace the missing oil of the skin. In women, washing the head once a fortnight will usually suffice. In mild cases it is better to give a lotion containing a small amount of oil, such as will be described presently, while in the more severe cases it will be advisable to use an ointment. In women the lotion should always be used.

In the bacterial cases washing should be more frequent, twice to three times a week in men, and once a week in women. Ext. quillaiæ liq. (B.P.C.) is an excellent shampoo lotion, but any good soap may be used for the purpose. Medicated soaps have no special value and the stronger spirit soaps are better avoided. Mild antiseptic lotions should be applied daily: resorcin is one of the best, but should not be used in people with white or fair hair, as it stains a greenish colour. A usual formula is: ℞ Resorcin ʒi., sp. coloniensis ℥i., ol. ricin. ʒii., aquam ad ℥viii. Hydrarg. perchlor. gr. ii., or chloral hydrate ʒi., may be substituted for the resorcin or combined with it if desired. These lotions should be massaged into the scalp once daily, and always after washing the scalp. In more severe cases it may be necessary to prescribe an ointment. The best basis for this is the combination of soft paraffin and cocoanut oil suggested by Whitfield, which is not messy and is easily washed out of the scalp; it has the disadvantage of getting very liquid in hot weather, and though this does not limit its efficacy it makes it difficult of transport. The best antiseptics to use are sulphur and salicylic acid, and a useful formula is: ℞ Ac. salicyl. gr. xv., sulphur. sublim. gr. xv., ol. lavand. ♏iv., paraff. moll. ʒii., ol. cocois nucifer. ad ℥i. Crocker's formula of resorcin, sulphur, and thymol, prescribed as ℞ Ung. thymol. co. dilutum (B.P.C.) is also very useful, but has a lanoline basis which is disagreeable to some people. In this condition, too, it is rarely necessary to use ointments in women.

Pityriasis Steatoides. — Pityriasis steatoides is merely an exaggerated form of the bacterial type of pityriasis simplex with some exudation. The scales are greasy and more profuse, but there is no associated redness of the underlying scalp. Sabouraud considers that in this condition the infection is due to the bottle bacillus acting in symbiosis with the *Coccus cutis communis*. The treatment is the same as for the last-named condition, but caution is required to prevent irritation of the scalp or an acute seborrhœic dermatitis may be precipitated. In addition to the drugs already mentioned, tar is of considerable value: it may be used alone or in combination with other antiseptics. A good formula is ℞ Anthrasol gr. xx., ac. salicyl. gr. v., paraff. moll. ʒii., ol. cocois nucifer. ad ℥i.

Acute Seborrhœic Dermatitis of the Scalp.—In this condition redness of the scalp occurs associated in the milder cases with greasy scales and in the more severe cases with weeping and crusting. The condition is usually only a more acute type of pityriasis steatoides. It is well to cut the hair as short as possible, though in less severe cases in women this can usually be avoided. Soaps should not be used, but scales and crusts should be removed by bathing in warm water or warm alkaline solution made by adding a teaspoonful of washing soda to a wash-hand basin of water. If the crusts are very thick, starch poultices are called for. In the more acute cases ℞ Hydrarg. perchlor. gr. i., linamentum calcis ad ℥viii., is a useful application, or if mercury is not well tolerated sulphur. præcip. ʒi., or acid. salicyl. gr. xxx., may be used instead. In the milder cases tar ointment may be used. As the inflammation subsides the treatment recommended for pityriasis steatoides may be employed.

Seborrhœa Capitis.

This is a state of excessive oiliness of the scalp, and varies from a slight greasiness of the hair to a condition in which the hair follicles are filled with greasy plugs, and the scalp is covered with a fatty exudate. The condition is due to over-activity of the sebaceous glands, and may occur alone or in conjunction with pityriasis steatoides. It usually begins about puberty, being most severe in early adult life and diminishes thereafter as age advances. Certain metabolic disturbances may be partly responsible for the condition, though racial and familial influences also play a part, and it is therefore necessary to rectify, if possible, any general metabolic disturbance, particularly by regulating the diet. Local treatment consists of frequent washing of the scalp, as described above, and the application of astringent and antiseptic preparations. The most suitable are alcoholic lotions. Greasy preparations should obviously be avoided. Useful formulæ are: ℞ Resorcin ʒi., acid. acetic ℥ss., sp. vin. rect. ℥ii., aq. rosæ ad ℥viii.; or hydrarg. perchlor. gr. ii., sp. coloniensis ℥i., sp. vin. rect. ℥iii., aquam ad ℥viii.; or liq. calcis sulphuratæ (B.P.C.) ʒi., glycerin. ʒi., aquam ad ℥viii.

Loss of Hair.

Apart from general alopecia of the scalp, due to some acute illness, from alopecia areata, or from localised baldness due to inflammatory conditions of the scalp, loss of hair can roughly be divided into two groups: (1) calvities, which is only seen in the male, and consists of a progressive loss of hair, commencing on the crown of the head and the frontal region and going on to complete baldness of the top of the head; and (2) a general thinning of the hair, often most marked on the vertex, which is most commonly seen in women from the age of 30 onwards. The first-named condition is most frequently seen in middle-aged and old men, but in the premature form complete baldness of the crown may have taken place in the early 'twenties. This condition is thought by enemy, but as an adviser who saves him from accidents and teaches him how to master conditions which may lessen his efficiency, cause his retirement, and shorten his life. The author discusses in detail safety helmets, goggles, clothing, protective padding of machines against injuries, parachutes, and swimming jackets; he pleads for the provision of (1) a first-aid box, and (2) food and water in every plane, and asserts the need for an inquiry into every crash by a board, on which shall sit a medical officer, charged with the duty of examining the aviator's medical record, to see if an explanation of the disaster can be found there.

ACCLIMATISATION IN THE TROPICS.

IN presenting the play "White Cargo," which is now being performed in London, the author, Leon Gordon, states that he has made no conscious effort to create or eliminate sensationalism, but has attempted to portray the struggle for development in a country which steadily defies the encroaching civilisation, and where the reaction of an ever-shining sun breeds inevitable rot—a rot which penetrates not only the vegetation and inanimate objects, but the minds and hearts of the white men who attempt to conquer it. The symptoms of mental and physical decadence produced by residence in a hot and malarious district are, indeed, well reproduced. Acclimatisation in such an isolated and unhealthy area may mean simply mental and physical deterioration. A treatise,[1] published recently by a French author, reaches a similar conclusion as regards physique and morale in the tropical French colonies. He states that sojourners in the French tropics compare unfavourably with those in the British tropics, the chief reason being the lack of active exercise in the former. The Britisher plays games regularly all the year round, whereas the French colonist leads a uniform sedentary life. Possibly the Britisher is nearer to true acclimatisation thereby.

Perhaps in its most exact meaning acclimatisation is the process of becoming accustomed to a new climate and its conditions, with maintenance of full physical and mental vigour. The main difficulties in the way of acclimatisation in the tropics are evil influences of climate per se, parasites, unhygienic conditions, altered habits of life, altered social states, sedentary routine, over-indulgence in food, and last but not least, alcohol. Many have seen the tableaux in the Tropical Health section housed in the pavilion of His Majesty's Government at Wembley. These demonstrate how, by human effort intelligently directed, the "white man's grave" of 25 years ago has become a centre of health and prosperity. Indeed, there exist some tropical cities from which all the opposing influences enumerated, with the exception of climate, have been eradicated, at least in so far as some white men are concerned. Having reached this advanced state of sanitary and moral excellence, are we in a position to say that these white men have become fully acclimatised in the sense defined above? Judging from the evidence reviewed recently by such authorities as Prof. van Eijkman and Dr. Andrew Balfour, the answer must be No. In spite of our success in stamping out malarial and such-like parasites, and in introducing all kinds of outdoor and indoor exercise and other healthy recreation, there still remains the depressing effect on the nervous system with its states of exhaustion and psychical irritability, for which the only cure is a prolonged vacation in a temperate clime. Possibly we are now just beginning to see clearly these effects on the efficiency and nervous mechanisms of the white man, because formerly such symptoms were masked by concomitant tropical disease due to known bacteria and parasites. Very probably these nervous effects are due to continuous heat, although we must not forget the possibility of an unknown bacterial or parasitical agent. At present it would appear that brain-work, with its more sedentary and indoor conditions, leads sooner to nervous symptoms than an outdoor occupation such as planting. It is only by a clear understanding of the present position that we shall make any real advance towards maintaining our fellow countrymen in the tropics in the full mental and physical vigour to which they have been accustomed at home, and which alone spells content to the white man.

MEMORIAL TO THE LATE SIR WILLIAM MACEWEN.

THE movement, which took formal shape a month ago, in favour of the commemoration of the life and work of the late Sir William Macewen, was carried a stage further at a meeting of the General Committee of the Memorial Fund, held on June 26th, in the Hall of the Royal Faculty of Physicians and Surgeons, Glasgow. At the original meeting, held on May 22nd, it had been remitted to an executive committee to consider and report on the form or forms which the memorial should take. The executive were now able to present a unanimous report, which, with very slight verbal alteration, was adopted by the General Committee. It is proposed to apply the funds that may be raised to three main purposes, in the following order: 1. The provision of a bust of the late Sir William Macewen, by a sculptor of eminence, with a replica for presentation to Sir William's family. It is intended that the bust shall be placed in the University. 2. The establishment of a memorial lecture, or prelection, to be called the "Sir William Macewen Lecture, or Prelection"; this lecture to be delivered annually, or biennially, as funds may permit. It is intended, further, that this lecture should not be merely a memorial oration, but should deal with any branch or aspect of surgical science. 3. The foundation of a Macewen medal or prize in surgery, to be awarded annually. The decision as to whether this should be assigned to the class of surgery at Glasgow University or should be given a wider application has been deferred for further consideration. A preliminary report as to the probable cost of the bust and replica was made by Dr. A. Freeland Fergus, on behalf of the executive, and the General Committee desired the executive to make such arrangements as may be required to carry through the scheme. It was intimated that already a number of substantial subscriptions have been secured, though no circular has yet been issued. The executive of the Memorial Fund consists of the following: Dr. A. Freeland Fergus (chairman), Sir Hector C. Cameron, Sir John Reid, Prof. T. K. Monro, and Mr. J. H. Pringle (vice-chairmen); Colonel J. A. Roxburgh, Mr. William Gray, Prof. Graham Kerr, Prof. W. K. Hunter, Sir Archibald Craig, Dr. J. N. Marshall, Dr. George A. Allan, Dr. J. G. McCutcheon, Mr. James MacFarlane (treasurer), and Mr. Archibald Young (secretary). In view of the present holiday season, it was resolved that the executive should defer the issue of a circular until a little later in the year. The committee is prepared, however, to receive subscriptions now, and such subscriptions should be sent to the Hon. Treasurer of the Memorial Fund, Wesleyan-street, Glasgow.

WE regret to announce the death on June 30th, at the age of 69, of Prof. Charles Hunter Stewart, who held the Chair of Public Health at the University of Edinburgh.

THE following have been elected as members of the Dental Board of the United Kingdom: To represent qualified dentists, for England and Wales, Mr. W. H. Dolamore and Mr. W. R. Ackland; for Scotland, Mr. W. Guy; and for Ireland, Mr. J. J. Andrew. Mr. F. Butterfield and Mr. W. F. Bowen have been elected to represent dentists registered under the Act of 1921.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXVIII.

TREATMENT OF THE COMMONER AFFECTIONS OF THE SCALP.

Scurfiness.

IT is not proposed here to say anything about localised patches of scurfiness due to specific conditions such as ringworm, psoriasis, &c., but to deal only with those conditions which are usually included under the term pityriasis of the scalp. Two forms are recognised: a dry form (pityriasis simplex), and a moist or greasy form (pityriasis steatoides). In the former there is a simple hyperkeratosis of the scalp with desquamation, while in the latter some inflammatory exudate of serum has taken place among the scales, thus altering their character. There is, however, no hard-and-fast dividing line between the two conditions.

Pityriasis Simplex.—Pityriasis simplex may occur in children, not infrequently in infants, in whom it often first makes its appearance in the form of rings. It is, however, chiefly seen in adults, particularly in men. It is generally due to bacterial infection, the infecting agent being probably the bottle bacillus, but in some cases it is due simply to a deficiency in the normal oil secreted by the skin glands, as, for example, in xerodermia. A differentiation between the two types is not always easy, but the general dryness of the rest of the skin and hair should favour a diagnosis of the latter type. Microscopic examination of the scales is helpful but not conclusive, as the bottle bacillus is a normal saprophyte of the scalp.

Treatment will vary in the two conditions. It is obvious that if the skin is too dry repeated washings are not likely to help, whereas if a bacterial infection is present these may be of considerable value. In the former case, therefore, in boys and men, it is best to confine washing of the scalp to once a week, and to give some slightly oily preparation to replace the missing oil of the skin. In women, washing the head once a fortnight will usually suffice. In mild cases it is better to give a lotion containing a small amount of oil, such as will be described presently, while in the more severe cases it will be advisable to use an ointment. In women the lotion should always be used.

In the bacterial cases washing should be more frequent, twice to three times a week in men, and once a week in women. Ext. quillaiæ liq. (B.P.C.) is an excellent shampoo lotion, but any good soap may be used for the purpose. Medicated soaps have no special value and the stronger spirit soaps are better avoided. Mild antiseptic lotions should be applied daily: resorcin is one of the best, but should not be used in people with white or fair hair, as it stains a greenish colour. A usual formula is: ℞ Resorcin ʒi., sp. coloniensis ℥i., ol. ricin. ʒii., aquam ad ℥viii. Hydrarg. perchlor. gr. ii., or chloral hydrate ʒi., may be substituted for the resorcin or combined with it if desired. These lotions should be massaged into the scalp once daily, and always after washing the scalp. In more severe cases it may be necessary to prescribe an ointment. The best basis for this is the combination of soft paraffin and cocoanut oil suggested by Whitfield, which is not messy and is easily washed out of the scalp; it has the disadvantage of getting very liquid in hot weather, and though this does not limit its efficacy it makes it difficult of transport. The best antiseptics to use are sulphur and salicylic acid, and a useful formula is: ℞ Ac. salicyl. gr. xv., sulphur. sublim. gr. xv., ol. lavand. ♏iv., paraff. moll. ʒii., ol. cocois nucifer. ad ℥i. Crocker's formula of resorcin, sulphur, and thymol, prescribed as ℞ Ung. thymol. co. dilutum (B.P.C.) is also very useful, but has a lanoline basis which is disagreeable to some people. In this condition, too, it is rarely necessary to use ointments in women.

Pityriasis Steatoides. — Pityriasis steatoides is merely an exaggerated form of the bacterial type of pityriasis simplex with some exudation. The scales are greasy and more profuse, but there is no associated redness of the underlying scalp. Sabouraud considers that in this condition the infection is due to the bottle bacillus acting in symbiosis with the *Coccus cutis communis.* The treatment is the same as for the last-named condition, but caution is required to prevent irritation of the scalp or an acute seborrhœic dermatitis may be precipitated. In addition to the drugs already mentioned, tar is of considerable value: it may be used alone or in combination with other antiseptics. A good formula is ℞ Anthrasol gr. xx., ac. salicyl. gr. v., paraff. moll. ʒii., ol. cocois nucifer. ad ℥i.

Acute Seborrhœic Dermatitis of the Scalp.—In this condition redness of the scalp occurs associated in the milder cases with greasy scales and in the more severe cases with weeping and crusting. The condition is usually only a more acute type of pityriasis steatoides. It is well to cut the hair as short as possible, though in less severe cases in women this can usually be avoided. Soaps should not be used, but scales and crusts should be removed by bathing in warm water or warm alkaline solution made by adding a teaspoonful of washing soda to a wash-hand basin of water. If the crusts are very thick, starch poultices are called for. In the more acute cases ℞ Hydrarg. perchlor. gr. i., linamentum calcis ad ℥viii., is a useful application, or if mercury is not well tolerated sulphur. præcip. ʒi., or acid. salicyl. gr. xxx., may be used instead. In the milder cases tar ointment may be used. As the inflammation subsides the treatment recommended for pityriasis steatoides may be employed.

Seborrhœa Capitis.

This is a state of excessive oiliness of the scalp, and varies from a slight greasiness of the hair to a condition in which the hair follicles are filled with greasy plugs, and the scalp is covered with a fatty exudate. The condition is due to over-activity of the sebaceous glands, and may occur alone or in conjunction with pityriasis steatoides. It usually begins about puberty, being most severe in early adult life and diminishes thereafter as age advances. Certain metabolic disturbances may be partly responsible for the condition, though racial and familial influences also play a part, and it is therefore necessary to rectify, if possible, any general metabolic disturbance, particularly by regulating the diet. Local treatment consists of frequent washing of the scalp, as described above, and the application of astringent and antiseptic preparations. The most suitable are alcoholic lotions. Greasy preparations should obviously be avoided. Useful formulæ are: ℞ Resorcin ʒi., acid. acetic ℥ss., sp. vin. rect. ℥ii., aq. rosæ ad ℥viii.; or hydrarg. perchlor. gr. ii., sp. coloniensis ℥i., sp. vin. rect. ℥iii., aquam ad ℥viii.; or liq. calcis sulphuratæ (B.P.C.) ʒi., glycerin. ʒi., aquam ad ℥viii.

Loss of Hair.

Apart from general alopecia of the scalp, due to some acute illness, from alopecia areata, or from localised baldness due to inflammatory conditions of the scalp, loss of hair can roughly be divided into two groups: (1) calvities, which is only seen in the male, and consists of a progressive loss of hair, commencing on the crown of the head and the frontal region and going on to complete baldness of the top of the head; and (2) a general thinning of the hair, often most marked on the vertex, which is most commonly seen in women from the age of 30 onwards. The first-named condition is most frequently seen in middle-aged and old men, but in the premature form complete baldness of the crown may have taken place in the early 'twenties. This condition is thought by

Sabouraud to be mainly due to seborrhœa capitis; many other factors have been invoked, of which heredity is the chief, but it is quite clear that no theory is completely satisfactory. A great deal can be done by preventive treatment, but this, to be of any value, must be commenced at an early age. In fact, general attention to the hygiene of the scalp from childhood is the best preventive of premature alopecia. This should consist of regular weekly washing of the scalp. The hair should be kept fairly short, and undue dryness or greasiness dealt with on the lines suggested above. Each individual should use only his own brush and comb, which should be washed frequently. The brush should not be too hard. People should be encouraged to patronise only those hairdressers who sterilise their instruments between each customer, and who provide a freshly sterilised brush for each individual. All violent treatment of the scalp, as by the machine-brush, should be condemned. The use of hair lotions, &c., of unknown composition should be avoided. When any evidence of excessive hair loss appears, gentle massage of the scalp may be practised and rubifacient lotions used, a favourite one being: ℞ Acetum cantharides ʒii., sp. coloniensis ℥ss., sp. vin. rect. ℥iss., aquam ad ℥viii. Pilocarpine is claimed to have a specific action, and may be used as follows: ℞ Pilocarpin. nitr. gr. xx., sp. rosmarin. ℥ss., alcohol (60 per cent.) ad ℥viii. There is little evidence that any of the many vaunted remedies for this type of baldness—vibro-massage, high frequency, &c.—have any definite action; the first-named may occasionally set up an acute seborrhœic dermatitis. Ultra-violet light, by producing hyperæmia of the scalp, may have a slight action in stimulating hair growth, but it requires to be handled with very great care. There is no reliable evidence forthcoming of the value of internal remedies in this condition.

While this type of alopecia does not appear to be associated with any derangement of the general health, the general thinning of the hair seen commonly in women is often associated with some general disturbance. Disturbances of function of the nervous system, the genital organs, the gastro-intestinal tract, or the thyroid may be associated with hair loss. Apart from correcting these errors, the scalp should be kept in a healthy condition on the lines already indicated. Doubtless in a few years' time it will be unnecessary to differentiate between the sexes, but at the present time for those girls who wish to let their hair grow long, careful brushing night and morning will help to keep the hair in good condition.

A. M. H. GRAY, C.B.E., M.D. Lond., F.R.C.P. Lond.,
Physician in charge, Skin and Venereal Disease Departments, University College Hospital.

THE appointments held by Mr. F. A. Williamson-Noble, the author of No. LXXVII. of this series, on the Treatment of Conjunctivitis, are assistant ophthalmological surgeon to the Westminster Hospital and assistant surgeon to the Central London Ophthalmic Hospital, and not as previously stated.

TREDEGAR HOSPITAL, MONMOUTHSHIRE.—A new operating theatre, the gift of the directors of the Tredegar Iron and Coal Company, has been added to the Tredegar Hospital, Monmouthshire.

WESTMINSTER HOSPITAL REOPENING.—As we announced on April 12th, Sir H. M. Mallaby-Deeley offered to double all the contributions received for the Westminster Hospital from April 2nd to June 30th, up to a total of £16,000. This sum has now been received in contributions, with the result that Westminster Hospital will be reopened on July 15th with 230 beds in what is practically a new building equipped with every modern improvement for the treatment of patients. It is satisfactory also to know that the hospital will open free of any debt incurred by the reconstruction of the building, inasmuch as £70,000, the cost of rebuilding, have been met by voluntary subscriptions.

DISINFECTION BY THE MUNICIPALITY AND BY THE HOUSEWIFE IN SCARLET FEVER AND DIPHTHERIA.

A CONTRAST.

BY DUNCAN FORBES, M.B.E., M.D., CH.B., B.SC. EDIN., D.P.H.,
MEDICAL OFFICER OF HEALTH FOR BRIGHTON.

IN the 'eighties and 'nineties and the first few years of this century the infections of scarlet fever and diphtheria were believed to be conveyed largely by direct contact with clinical cases and in no small degree by infected articles. To control the spread of these diseases fever hospitals were built for the isolation of patients and careful disinfection followed the removal of the patient to hospital. The campaign to stamp out these two diseases was carried on with commendable vigour. Even only children who could have a room to themselves and be looked after by their mother at home were sent into the fever hospital, and the higher the percentage removal to hospital the more hopeful was the medical officer of health of controlling spread. Disinfection was also thoroughly carried out, the patient's and mother's clothing, the mattress and bedding, the contents of wardrobes, chests of drawers, boxes, all curtains and hangings, and carpets were removed for disinfection by steam, and the walls, ceiling, and floor of the room were sprayed with disinfectant. When a return case was reported a systematic search was made for articles which had not been disinfected and had been taken out on the return home of the patient, as these non-disinfected articles were considered probable causes of return cases.

With the failure of isolation in hospital and of thorough disinfection to stop the epidemic prevalence of these diseases, with increased evidence of the dangers arising from the carrier and the missed case—more dangerous than the clinical case because of their wider sphere of action—the hospital came to be considered as a convenient, although expensive, centre for the treatment of these diseases and only necessary for isolation in special cases—for instance, from boarding houses, resident schools, the families of milkmen, teachers, overcrowded houses, and so forth. Disinfection for the same reasons was less and less considered an important factor in the prevention of spread, especially as proof accumulated that the organisms of many acute diseases are delicate and die quickly outside of the body. For these reasons fewer articles were removed for steam disinfection, carpets, hangings, and even the mother's dress were disregarded, and in many cases only the bedding, including the mattress, and the personal clothing were removed. Similarly spraying of rooms became less common and was in some cases replaced by a perfunctory disinfection by gas, the latter in order that something could be said to have been done.

In substituting cleansing and disinfection by the housewife for municipal disinfection I was influenced by the considerations set out above, chiefly perhaps by picturing immense numbers of constantly escaping active organisms in the carrier and comparing these with scattered organisms living under adverse conditions outside the body and dying in great numbers. My conclusion was that infection was due to the reception of organisms in massive dose from hands, handkerchiefs, towels, and such-like, and within a short period of their escape from the carrier. Having come to this decision, I consulted two well-known bacteriologists, who agreed that in scarlet fever and diphtheria the present methods of disinfection might safely be discontinued. Further, in conversations with other medical officers of health, I found that most agreed that mattress disinfection usually accomplished no useful purpose and that the spraying of walls was unnecessary.

Instructions as to Cleansing and Disinfection after Scarlet Fever and Diphtheria.

The first step taken in 1909 was the stopping of the steam disinfection of the bedding and mattress, when a pamphlet of instructions to the following effect was left with the parent:—

As the infection comes chiefly from the throat and nose the following measures must be taken immediately after the removal of the patient.

1. All bedclothes and particularly sheets, pillow-slips, and handkerchiefs which are in *contact with the nose and mouth* must be put into water at once and washed,* linen and cotton goods being brought to the boil in soapy water. The above applies equally to the attendant's clothes.
2. All feeding and drinking utensils used by the patient must be kept apart and be placed in boiling water for five minutes and then be thoroughly rinsed and cleansed.
3. All pens, pencils, toys, and books used by the patient whilst ill are best burnt if of little value. On the other hand, if the parents prefer it (*a*) pens and pencils can be put in boiling water for a few minutes; (*b*) many toys can be boiled or thoroughly washed. Books are difficult to disinfect, so if of value, or if they belong to a library, the parents should have them called for from this office.

The Rooms Used by the Patient must be Spring-cleaned.

If the above instructions are carefully attended to there is no need to spray or fumigate the bedroom or to move bedding for steam disinfection; such spraying and stoving will only be undertaken if the cost is paid in advance. When the inspector calls to see that cleansing has been thoroughly carried out he will be pleased to advise on any doubtful point.

* To send goods *which have been exposed to infection* to a laundry except notice is given that they have been exposed to infection and except proper precautions are taken in transmission, renders the sender liable to prosecution.

An 11 years' trial was given to this experiment and then, in May, 1921, a further step was taken. Up to that time rooms had been sprayed, thereafter even that was stopped.

Much discussion has recently taken place as to the advisability of giving up municipal disinfection, and I am surprised to find how little is claimed for it by those who advocate its continuance. Briefly, their argument is as follows: "Disinfection by the local authority may not do much good, it cannot do harm; even if it saves an occasional case which will not affect the position statistically it is still worth doing." I venture to disagree with these statements. In the first place I think that reliance should be placed on the available statistics until further proof is forthcoming. It is for this reason that I have set out shortly the Brighton figures collected over many years.

Brighton Statistics.

A = Disinfection by the municipality, 1900–09 inclusive.
B = Municipal disinfection stopped but rooms sprayed, 1910–20 inclusive.
C = Disinfection and cleansing entirely by housewife, 1921–24, three years.

—	Cases removed and cases per 1000 of population.	Day on which subsequent case occurred—					Total after seventh day.
		0–7	8–14	15–21	22–35	35 +	
A	2103 Per 1000	85 40·4	18 8·6	10 4·8	5 2·4	4 1·9	37 17·6
B	3027 Per 1000	119 39·3	27 8·9	12 4·0	7 2·3	5 1·6	51 16·8
C	752 Per 1000	21 27·9	10 13·3	2 2·7	— —	1 1·3	13 17·3

These statistics, so far as they go, show that disinfection by the local authority presents no advantages over cleansing. The figures are small, and it would be absurd to consider that they prove conclusively anything one way or other, but they are the only figures available to me and they are sufficient to provide reasonable grounds for the trial of cleansing and disinfection by the housewife in other towns. That is really all I hope for—namely, that the experiment will be given a fair trial in a number of towns and that all of us will keep an open mind on the subject until the accumulation of figures leaves no reasonable ground for doubt as to which method is the better. In this connexion I would suggest that the Ministry of Health or the Society of Medical Officers of Health should arrange for the collection of statistics from many towns, the medical officers of which agree to follow out one or other method strictly.

The "disinfectors" no doubt will say, "Why abandon disinfection which can do no harm?" The reply is, "It is not proved that the orthodox method does no harm." Personally I believe that it may do serious harm. A child is removed to hospital and the floor and walls of the bedrooms, and it may be the living-room, are thoroughly wetted What more likely in winter, when these diseases are most prevalent, that carriers develop colds and become more infectious. Also the disinfection leads frequently to the closing for the following night of the child's bedroom and the crowding of the other members of the family together, again adding to the danger of infection from the carrier. But apart from this and of greater importance is the fact that the public are not educated and are given a false sense of security. They say, "Disinfection has been thoroughly carried out at great expense and trouble, what more is wanted?" On the other hand, when no disinfection is carried out by the municipality the public learn to rely on themselves, they learn what is the chief danger, and how they themselves can help in preventing the spread of the disease; they receive no sense of false security, and in our experience are the more willing to be taught. In addition, I need hardly point out that the funds available for health work at the present time are limited and that money spent in disinfection curtails work in other directions.

It is admitted that it is a hard thing to abandon old customs and to admit that for years money may have been spent needlessly and advice may have been wrongly given, but persistence in a doubtful course will do more harm to our prestige in the long run than a sincere endeavour to get at the truth and act accordingly whatever the immediate consequences.

TUBERCULOSIS.

Vaccination against Tuberculosis.

Dr. A. Calmette has long urged the view that the control of tuberculosis depends on preventing the dissemination of the bacilli by treating every tuberculous man or animal, however slightly affected, as a potential source of danger and on being able to protect artificially the susceptible individuals by some method of vaccination. The former part of his programme is largely a question of the cultivation of public opinion and the practicability of administrative control. The latter part depends in the first instance on animal experimentation, to which he has applied himself for many years with varying, but never really very substantial, success. He now, in conjunction with Dr. C. Guérin, reports[1] a series of observations on calves in which most encouraging results have been obtained. The animals received when quite young a large dose, 50 or 100 mg., of a non-virulent live culture subcutaneously and subsequently, at intervals varying from 1 to 18 months, resisted an intravenous dose of virulent organisms to which the controls all succumbed. The vaccinating strain was originally a very virulent bovine culture, which since 1908 has been continuously grown on potato cooked in ox-bile with 5 per cent. of glycerine. After 13 years and some 230 subcultures this strain was found to have lost virulence for all species of animals: 10 mg. will not infect a guinea-pig and by no route of introduct will it cause the formation of tubercles. On the hand, it has a certain amount of toxicity, tube of an ordinary potency can be prepared from

Having come to this decision, I consulted two well-known bacteriologists, who agreed that in scarlet fever and diphtheria the present methods of disinfection might safely be discontinued. Further, in conversations with other medical officers of health, I found that most agreed that mattress disinfection usually accom-

THE CHOICE OF A MOTOR-CAR.

BY J. MARSHALL, M.I.A.E.,
LONDON MANAGER OF MESSRS. MANN, EGERTON AND CO., LTD., OFFICIAL CONSULTING ENGINEERS TO THE MEDICAL INSURANCE AGENCY.

THE choice of a car presents generally a difficult problem to the doctor. The type of practice, whether in town or country, and the state of the roads to be covered, whether the practice is in a flat or hilly district—these are among the many points which have to be carefully studied.

Initial Cost.

The price of the car is usually that which is considered first, and very often this must be arbitrarily decided without regard to other points involved. Even when but little capital is available, it must be remembered that to pay a good price may, for various reasons, be in the end more profitable than to buy a very cheap car, and with the deferred payment system described below it is not necessary to produce all the purchase money at once. Providing that the car selected is of sound workmanship and good repute, it will be found that the yearly depreciation is much lower in a more expensive car than in one of cheaper quality.

Depreciation.—The question of depreciation has some bearing on the type of body chosen. At the present time, owing to trend of fashion, the car with the best second-hand selling value is the saloon, and this appears likely to continue for some little time. Generally speaking, particularly in the larger type of car, the three-quarter landaulette, and especially the "all-enclosed" pattern, have extraordinary good second-hand value for many reasons. This car can be owner-driven and has a further market in that it can be used eventually for private hire work; it lasts considerably longer, and without undue rattle, than the coach-built "all-weather" or "cabriolet" type, which runs the saloon so closely in favour.

If a good car of the touring body type is bought with the intention to keep it during its lifetime, which should be at least 10 years, only 10 per cent. for depreciation need be allowed, as the car after that period will always bring some price. If, however, it is only intended to keep it for a few years, 20 per cent. will have to be allowed for the first year. On a car which costs approximately £500 there is a depreciation of some 20 per cent. each four years of its life, whereas a cheap car would depreciate very much more the first year. This applies particularly to American cars, which have to be depreciated at least 10 per cent. per annum more than the average British car.

American and British Cars: The McKenna Duties.

Owing to the larger horse-power of American cars in relation to their seating capacity and weight, they naturally use more petrol and oil, and are consequently more expensive to run than the smaller engined British car. The average small car up to 11 h.p. should do normally approximately 34 miles per gallon, but in the case of medical men stops are so frequent that petrol consumption cannot be reckoned on normal lines; and therefore I would not unduly stress this point as a factor in the choice of a car, but would rather consider the question on the lines set forth below. The price of petrol is, anyhow, so low that a few miles per gallon one way or the other is not very vital. Naturally, if a comparatively large car is decided on it must be realised at the outset that the costs of running will be considerably increased, particularly in the direction of licence and insurance, which are two of the heaviest dead charges that come against upkeep. There may be other factors to be considered, whose weight is not easy to assess, in connexion with the class of practice hoped for. A well-appointed car, larger and more luxurious in fittings than is really required, may be an asset to a practitioner in a fashionable neighbourhood, where it could only be an incubus to a man with a large panel practice or whose patients belong chiefly to the middle classes. Young consultants may be wise to spend more as initial outlay and should disregard small differences of running costs, whereas the general practitioner whose car will have continued hard use will not need a car with a large engine unless his work is scattered in a mountainous area. For the low speed and constant stopping involved in a morning round a car with from 10–15 h.p. will serve admirably, and for this class of work it is hardly worth while having a six-cylinder car of 20–40 h.p.

The position created by the proposed removal of the McKenna duties on August 1st has now been regularised, and no advantage can be looked for by delaying the purchase of a car until after that date. Prices have been settled on one or other of the following bases: (*a*) By the definite reduction and publication of the new prices; (*b*) by a guarantee to cover a drop in price between now and August 1st; (*c*) by an arrangement whereby cars can be purchased now at an agreed price and collected from bond on August 1st. These three clauses cover all foreign cars. In regard to the larger question of the British-made car, no reduction need be looked for; owing to reduced production prices are much more likely to be increased. Incidentally some misconception has been apparent in regard to the effect on retail prices of the removal of the McKenna duties; it was anticipated by the public that 33⅓ per cent. would be taken off the list price of the car, but probably the most that has been given is 10 per cent. It is permissible to point out that the duty of 33⅓ per cent. is taken off the actual manufacturing costs of the article in the country of its origin, whereas freights and costs of handling to this country were not affected. This explains the difference between the concession given by the manufacturers and the percentage of the tax removed.

Deferred Payments.

The deferred payment system can be recommended to those who do not feel disposed to release securities but prefer to pay for a car out of income. There are many forms of this system, which involve an increase of from 2½ per cent. to 4 per cent. on the original cost of the car with a 25 per cent. deposit or a 50 per cent. deposit, and the balance at 5 per cent. per annum spread over any time up to two years and may be payable by either monthly or quarterly instalments. No capital security for the purchase price is demanded, inquiry being addressed to the purchaser's bank merely to ensure that he is "good for" the monthly or quarterly sum payable. Providing a reasonable and honest firm is dealt with no trouble is likely to arise. On the other hand, it should be remembered that all payments due, whether monthly or quarterly, should be adhered to. If they are not, the car could be claimed back with the consequent loss to the purchaser of the whole of his deposits. In passing, it might be said that no reputable firm would insist on the strict letter of the law, but it is essential for the purchaser to bear this point in mind.

Income-tax deductions are allowed on some part of the instalments paid when the car is purchased on the deferred payment system. Each instalment must be split up for the purpose of income-tax into two portions, one portion being the amount estimated as a payment for the hire of the car until it becomes the property of the purchaser, and the other portion being the amount paid towards the purchase price. The best practice is to add up the total amount of all the instalments payable, and to deduct from this total the net cash price at which the car could have been bought outright. The difference between the two sums is the total amount attributable to hire, and it should be then split up and spread over the number of years during which the agreement is current.

it is antigenic in the sense that inoculation excites the formation of antibodies demonstrable by complement fixation. The test dose was 5 mg. of a virulent bovine culture injected into the jugular vein, the virulence being such that 1/250 mg. would kill a guinea-pig.

It remains to work out in detail the exact reasons why these experiments have succeeded where so many others have failed. It seems fairly clear that the most important factor is the introduction of live bacilli which will not cause infection but will survive in the tissues till they are destroyed by the natural processes of phagocytosis and digestion, through which foreign particles in the tissues are ultimately got rid of or are eliminated by the bowel or in milk. Dr. Calmette looks upon the relation of such organisms to the tissues of the host as of the nature of a symbiosis; so long as the bacilli live, so long will the host be stimulated to protect itself against either an outbreak of virulent bacilli, which may be lying latent somewhere in the body, or the introduction of infecting organisms from outside. But he regards the protection as dependent on the continued life of the vaccinating bacilli and advises that cattle should be dosed soon after birth and thereafter annually. Another point which may have helped to determine the successful issue is the large size of the vaccinating dose. There appear, however, to be no data to determine the influence of this factor or its relation to the duration of resistance.

The complete control of bovine tuberculosis would make a good deal of difference to tuberculosis in children. It may be that Dr. Calmette's vaccine will give comparable results when applied directly to human infection. There is no reason to doubt the soundness of the common belief that small doses of live bacilli in childhood do actually confer a certain amount of resistance to subsequent infection. Proposals have often been canvassed for reproducing this observational phenomenon in man; how far they have been actually tried is uncertain, though if any definite success has been achieved it has not been published. The complete loss of virulence of Calmette's bile culture seems fully established and its application to man is not beyond the bounds of reasonable human hygiene.

An Indictment of X Ray Treatment of Surgical Tuberculosis.

The discussion on actinotherapy in tuberculosis at a recent meeting of the Danish Medical Society in Copenhagen seems to have resolved itself, according to the official report,[2] into a spirited indictment and defence of X ray treatment. Dr. Axel Reyn, the head of the Finsen Institute, was the chief witness for the prosecution, and he was the better able to portray X ray treatment in a lurid light for having at his disposal many cases of X ray lesions sent to the Finsen Institute for repair. Finsen light, it would seem, is one of the best remedies for X ray burns and other X ray injuries, and it is therefore natural that the sins of all the Danish X ray specialists and X ray dilettantes should finally come to roost at the Finsen Institute. X ray treatment has been given at the Finsen Institute, as well as other forms of actinotherapy, but the results have not been so good as after treatment with concentrated or diffuse carbon arc-light. In the period 1910-20 there were 553 cases of tuberculous adenitis treated partly with the X rays and partly with carbon arc-light baths, supplemented by concentrated carbon arc-light on fistulæ. Recovery was effected in 98 per cent. of the cases treated with carbon arc-light, and in only 40 per cent. of the cases treated with the X rays. The arc-light bath was found to have a remarkably vitalising effect, restoring general bodily and mental vigour to the patient. Dr. Reyn was not in favour of abandoning X ray treatment altogether, and he suggested that in small doses, which were certain not to harm, they might be a useful supplement to other methods. Several of the speakers who followed him held very different views as to the dangers of X ray treatment, and one of them referred to re-examinations he had made of patients given X ray treatment between 1920 and 1922 for tuberculous glands. He had faced these patients again in fear and trembling, but he had been rejoiced to find that though an interval of at least a year and three months had elapsed since the X ray treatment had been given, there was no case in which serious X ray changes in the skin could be found. Both the opponents and supporters of X ray treatment found themselves on common ground when the discussion veered round to the dilettante radiologist. There were, of course, no dilettante radiologists speaking as such at this discussion, and there was not a discordant note when one speaker after another referred in terms more vigorous than polite to the physician who believes that he has but to purchase an X ray plant in order to blossom out as a radiologist.

The Papworth Tuberculosis Colony.

The last report of this colony, presented at the seventh general meeting, is full of the buoyant faith which have been among the chief sources of the colony's vitality. In almost every respect the colony has doubled itself since the preceding year, and there are now 196 persons settled in the village, including 70 children. Only in one of these 70 children has evidence of tuberculosis been found, and Dr. P. C. Varrier-Jones sees in this observation the prospect of rearing from tuberculous stock a new generation both tubercle-free and resistant to tubercle. The work allotted to the patients is never useless and is always chosen so as to suit the strength and inclinations of the patient, whose wages rise as his health improves and his working hours approximate to those of an able-bodied man. The inhabitants of Papworth need not ration their ambitions any more than a corporal in Napoleon's army, and as the ex-patient's skill increases, he has the opportunity to gain both financially and in status in his particular industry. "The big jobs are open to him as well as the small ones. There are no highly paid fit men acting as officials in the industries, all such posts are held by ex-patients. . . ." As in previous reports, Dr. Varrier-Jones gives an account of each of the main industries such as carpentry, poultry-farming, gardening printing, sign-writing, cabinet-making, upholstering, portmanteau and boot-making, tailoring, hand-made jewellery, and leather work. Almost every occupation seems to be represented at Papworth.

There is a point on which this report is not as communicative and instructive as it might be. It would be interesting to learn how many, or what proportion, of the patients entering Papworth settle there as permanent colonists. A clue, but only a clue, to this point is to be found in the statement that "the total number of inhabitants now settled in the village is 196. . . . The number of admissions to the central institution and Homeleigh during 1923 has been 222." Further information on this point would be of great value in estimating the approximate number of patients who would "make good" in colonies of this kind, supposing the Papworth model is accepted as satisfactory, and the copying of this model elsewhere is found desirable. It has been argued that many, perhaps most, consumptives sooner or later hanker for the comforts, or rather the discomforts, of their old homes, even though they be in squalid surroundings. To rub shoulders with the able-bodied man in the street and not always to be associated with one's fellow-sufferers are cravings which some patients experience. It is a pity that when the Anglo-Saxon acquires tubercle he cannot always discard his vagrant temperament.

DR. ATKIN SWAN MEMORIAL FUND.—A fund has been opened for a memorial to the late Dr. Charles Atkin Swan, with the object of endowing a Dr. Atkin Swan cancer bed at St. George's Hospital, London. The sum required is about £1000, and contributions may be sent to the fund at Westminster Bank, 1, Cavendish-square, W. 1.

THE CHOICE OF A MOTOR-CAR.

BY J. MARSHALL, M.I.A.E.,
LONDON MANAGER OF MESSRS. MANN, EGERTON AND CO., LTD., OFFICIAL CONSULTING ENGINEERS TO THE MEDICAL INSURANCE AGENCY.

THE choice of a car presents generally a difficult problem to the doctor. The type of practice, whether in town or country, and the state of the roads to be covered, whether the practice is in a flat or hilly district—these are among the many points which have to be carefully studied.

Initial Cost.

The price of the car is usually that which is considered first, and very often this must be arbitrarily decided without regard to other points involved. Even when but little capital is available, it must be remembered that to pay a good price may, for various reasons, be in the end more profitable than to buy a very cheap car, and with the deferred payment system described below it is not necessary to produce all the purchase money at once. Providing that the car selected is of sound workmanship and good repute, it will be found that the yearly depreciation is much lower in a more expensive car than in one of cheaper quality.

Depreciation.—The question of depreciation has some bearing on the type of body chosen. At the present time, owing to trend of fashion, the car with the best second-hand selling value is the saloon, and this appears likely to continue for some little time. Generally speaking, particularly in the larger type of car, the three-quarter landaulette, and especially the "all-enclosed" pattern, have extraordinary good second-hand value for many reasons. This car can be owner-driven and has a further market in that it can be used eventually for private hire work; it lasts considerably longer, and without undue rattle, than the coach-built "all-weather" or "cabriolet" type, which runs the saloon so closely in favour.

If a good car of the touring body type is bought with the intention to keep it during its lifetime, which should be at least 10 years, only 10 per cent. for depreciation need be allowed, as the car after that period will always bring some price. If, however, it is only intended to keep it for a few years, 20 per cent. will have to be allowed for the first year. On a car which costs approximately £500 there is a depreciation of some 20 per cent. each four years of its life, whereas a cheap car would depreciate very much more the first year. This applies particularly to American cars, which have to be depreciated at least 10 per cent. per annum more than the average British car.

American and British Cars: The McKenna Duties.

Owing to the larger horse-power of American cars in relation to their seating capacity and weight, they naturally use more petrol and oil, and are consequently more expensive to run than the smaller engined British car. The average small car up to 11 h.p. should do normally approximately 34 miles per gallon, but in the case of medical men stops are so frequent that petrol consumption cannot be reckoned on normal lines; and therefore I would not unduly stress this point as a factor in the choice of a car, but would rather consider the question on the lines set forth below. The price of petrol is, anyhow, so low that a few miles per gallon one way or the other is not very vital. Naturally, if a comparatively large car is decided on it must be realised at the outset that the costs of running will be considerably increased, particularly in the direction of licence and insurance, which are two of the heaviest dead charges that come against upkeep. There may be other factors to be considered, whose weight is not easy to assess, in connexion with the class of practice hoped for. A well-appointed car, larger and more luxurious in fittings than is really required, may be an asset to a practitioner in a fashionable neighbourhood, where it could only be an incubus to a man with a large panel practice or whose patients belong chiefly to the middle classes. Young consultants may be wise to spend more as initial outlay and should disregard small differences of running costs, whereas the general practitioner whose car will have continued hard use will not need a car with a large engine unless his work is scattered in a mountainous area. For the low speed and constant stopping involved in a morning round a car with from 10–15 h.p. will serve admirably, and for this class of work it is hardly worth while having a six-cylinder car of 20–40 h.p.

The position created by the proposed removal of the McKenna duties on August 1st has now been regularised, and no advantage can be looked for by delaying the purchase of a car until after that date. Prices have been settled on one or other of the following bases: (*a*) By the definite reduction and publication of the new prices; (*b*) by a guarantee to cover a drop in price between now and August 1st; (*c*) by an arrangement whereby cars can be purchased now at an agreed price and collected from bond on August 1st. These three clauses cover all foreign cars. In regard to the larger question of the British-made car, no reduction need be looked for; owing to reduced production prices are much more likely to be increased. Incidentally some misconception has been apparent in regard to the effect on retail prices of the removal of the McKenna duties; it was anticipated by the public that 33⅓ per cent. would be taken off the list price of the car, but probably the most that has been given is 10 per cent. It is permissible to point out that the duty of 33⅓ per cent. is taken off the actual manufacturing costs of the article in the country of its origin, whereas freights and costs of handling to this country were not affected. This explains the difference between the concession given by the manufacturers and the percentage of the tax removed.

Deferred Payments.

The deferred payment system can be recommended to those who do not feel disposed to release securities but prefer to pay for a car out of income. There are many forms of this system, which involve an increase of from 2½ per cent. to 4 per cent. on the original cost of the car with a 25 per cent. deposit or a 50 per cent. deposit, and the balance at 5 per cent. per annum spread over any time up to two years and may be payable by either monthly or quarterly instalments. No capital security for the purchase price is demanded, inquiry being addressed to the purchaser's bank merely to ensure that he is "good for" the monthly or quarterly sum payable. Providing a reasonable and honest firm is dealt with no trouble is likely to arise. On the other hand, it should be remembered that all payments due, whether monthly or quarterly, should be adhered to. If they are not, the car could be claimed back with the consequent loss to the purchaser of the whole of his deposits. In passing, it might be said that no reputable firm would insist on the strict letter of the law, but it is essential for the purchaser to bear this point in mind.

Income-tax deductions are allowed on some part of the instalments paid when the car is purchased on the deferred payment system. Each instalment must be split up for the purpose of income-tax into two portions, one portion being the amount estimated as a payment for the hire of the car until it becomes the property of the purchaser, and the other portion being the amount paid towards the purchase price. The best practice is to add up the total amount of all the instalments payable, and to deduct from this total the net cash price at which the car could have been bought outright. The difference between the two sums is the total amount attributable to hire, and it should be then split up and spread over the number of years during which the agreement is current.

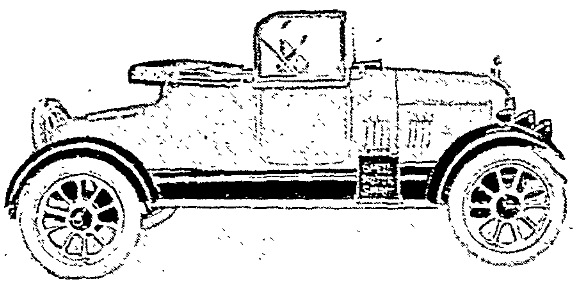
The annual amount thus ascertained *can be deducted* as a professional expense. Depreciation and a further deduction for repairs are also allowed, the amount being fixed by the income-tax authorities. The other portion of the instalments—i.e., those portions attributable to payment of the *purchase price*, are *not* allowed as a deduction from the profits.

The £200 Limit.

Motor Cycles.—The young energetic medical man may seriously consider the purchase of a good motor-cycle in place of a car. This is unlikely to be a wise investment, unless his work is carried on in a laboratory or an office and he requires a conveyance merely for purposes of recreation. For those in general practice the discomfort of a round in wet weather on a motor-cycle is intense, and, moreover, it is inadvisable to present oneself at a patient's house in mud-stained overalls. Again, even the most hardy nerves are likely to be upset in time by the excessive vibration which is experienced, and which one does not get on a car, however small.

Three-Wheel Type.—The three-wheel type of vehicle is becoming obsolete; from the point of view of a town practice it is entirely unsuitable owing to a difficulty in starting and a distinct tendency to skid. There would be no advantage gained by a purchase of this type of vehicle, as running costs can be considered practically equal to those of a small car. If existing garage arrangements will not permit of any other form of vehicle than the three-wheel, we would rather be inclined to extend the garage accommodation, if in any way possible, to take a small four-wheeler.

FIG. 1.



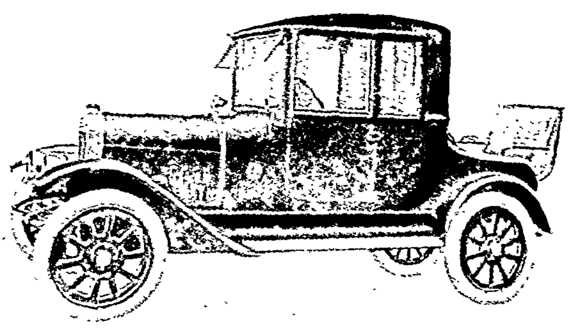
11·9 h.p. Morris-Cowley two-seater. Price £198. With side-curtains in use independently as side-screens.

The Small Car.—Some misconception is apparent amongst the average car buyers that because a small car may be cheap or low in price that it is necessarily no good. This is a complete fallacy. There are some small cars on the market which are perfectly reliable and will give good service to their owners for many years, always providing that due regard is given to the district in which they are likely to operate; for instance, it would not be good policy to purchase a 7 h.p. Austin, 7 h.p. Jowett, or 8 h.p. Rover for some of the wild and hilly moor practices in Yorkshire, although these would be perfectly suitable for the average town or country practice. A car suitable for the very rough, hilly country would be the Trojan or a Ford, although the latter is somewhat expensive in upkeep. At the same time it will give good service and stand a vast amount of rough usage. Among the sound cars obtainable for £200 or under are the Morris Cowley 11·9 h.p., the Clyno 11 h.p., and the Singer 10 h.p.

The £400 Limit; Higher-Priced Cars.

Cars between £200 and £400 are of a heavier type. Within reason, where an intending purchaser has the larger sum to spend, it is preferable to buy the better car for many reasons. It is more strongly built, the body-work is better, accessories more substantial, larger tyres are provided in relation to the horse-power. Grease gun lubrication, an essential point where too much time is not available for attending to the car, is also provided as a rule, and more power. The Calthorpe, 10 h.p. Calcott, 11.4 h.p. Citroën, Renault, Morris-Oxford, and 11 h.p. Standard are all sound examples of this type and may be relied upon to give good and efficient service for a number of years providing that ordinary care is given.

FIG. 2.



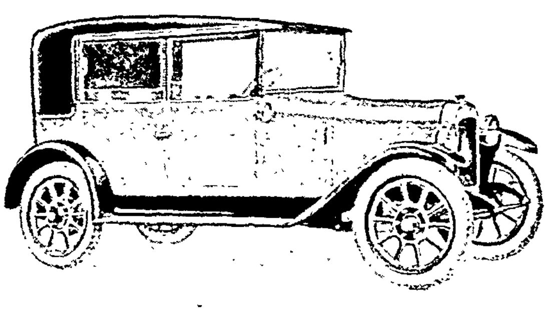
10–15 h.p. Calthorpe two-seater coupé. Price £350.

The choice of a car between £400 and £700 is not difficult. Such types as the 12 h.p. Austin, 14 h.p. Sunbeam, 14/40 h.p. Vauxhall, 15 h.p. Wolseley, 10/15 h.p. Fiat, 12 h.p. Rover, 14 h.p. Standard at once present themselves. Any of these can be confidently recommended, particularly on long-distance practices, or where a fairly large body is required for town use.

The Choice of Body.

The type of body preferred is largely a matter of individual taste. Generally speaking, for country work the best is a touring type (Fig. 1) with all-weather equipment. There are several excellent types on the market, and when completely closed the car is quite wind- and water-proof. For town work, some form of closed car is preferable—that is, a coupé (Fig. 2), all-weather (Fig. 3), or saloon (Fig. 4); this type of body adds slightly to the running cost, but not unduly so, owing to the fact that a comparatively slow pace has to be maintained in towns; it may safely be reckoned that town running costs at least 20 per cent. more than country. If a car is purchased with the all-weather type of body, it is essential that one should be selected with what is termed a steel head. Such a type is represented by the "Auster" or "Gwynne" head, in which practically no woodwork is used at all, and gives an extremely light body and the full effect of either an open touring car or the completely enclosed type. Providing this type is selected no trouble should be experienced with it for some years. But,

FIG. 3.



12 h.p. Austin "Harley" all-weather. Price £525.

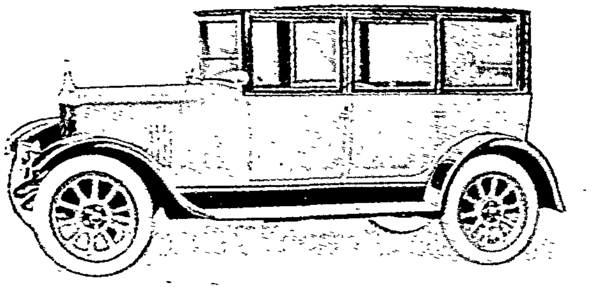
on the other hand, the disadvantages of the wooden pillar type cannot be too strongly emphasised.

Special Points about the Chassis.

Undersized tyres should be avoided at all costs for a number of reasons. If these are on the small side intense vibration will be felt throughout the car even on a fairly good road, and their life is short. An oversize should be fitted where roads are not good, or preferably, the new balloon type (Fig. 5), which on some makes of cars are fitted without extra cost. Much controversy has arisen over the question of these particular tyres, which are made by Dunlop, Michelin, and other well-known firms, but in my opinion the advantages outweigh the disadvantages, in that one gets freedom from vibration and slow rolling effect over very bad roads, with consequent reduction of undue strains on the chassis. On the other hand, there is a slight slowing of speed and steering is a little harder on sharp corners. In the course of a few months it will be possible to obtain replacements of these tyres in practically any town in the British Isles, so that no one need fear being stranded and unable to obtain a replacement. It may be taken as a general rule that cars are certainly not over-tyred, and practically any make will stand an oversize.

Frame.—Special attention should be paid to the frame of the chassis. This should be of generous dimensions, and for the novice can most easily be noticed by comparison. It should always be remembered that weight does not necessarily mean strength, and where a chassis is comparatively of very light construction the advice should be sought of a competent engineer or firm of repute. The Ford is quite a good example of a strong car of light construction. It is unwise to select a chassis with very low ground clearance—i.e., the distance from the lowest point of the chassis, which may either be the front axle or the bottom of the axle casing, should not be much less than 8 in. to 9 in., otherwise on rough roads or deep ruts damage may be done to the underparts of the chassis, involving heavy expenses in repairs.

FIG. 4.



14 h.p. Standard "Kensington" three-door saloon. Price £450.

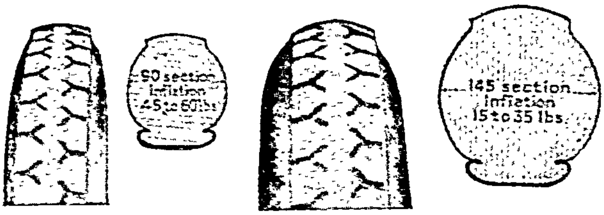
Accessibility of Parts.—General accessibility is essential, particularly in the case of the necessary greasers for various shackle pins on springs, brake-rocker, arms, &c., and the average up-to-date chassis is fitted with what is known as the Enots grease gun system (Fig. 6), which, by a turn of the wrist, can be fully charged without messiness.

Wheelbase.—Most cars have two wheelbases, the long and the short. The long is usually used for covered bodies, and the short for two or four seaters. There is little difference in the turning circle capabilities of either chassis on cars up to 15 h.p., but beyond that the long wheelbase has considerably extra weight, heavier running costs, and perhaps takes much wider space to turn in. Generally speaking, the long wheelbase chassis skids less than the short one.

Four Wheel Brakes.—These are a distinct advantage if they are or can be fitted to the particular model under consideration. They make for fast driving, and even on very greasy roads are quite safe. Cars can be pulled up at 40 miles per hour with all brakes on without a semblance of a skid.

Springs.—The only test of good springing is a ride in the car with the particular type of body that is being considered. What is termed hard springing can, of course, be considerably reduced by taking out one leaf from the back springs or fitting some form of rebound damper. These vary in price from a few shillings up to £15, according to the size of the car. They are quite effective and should invariably be fitted for bad or difficult country. Certain types of the cheaper priced cars are fitted with these as standard—for example, the Citroën.

FIG. 5.



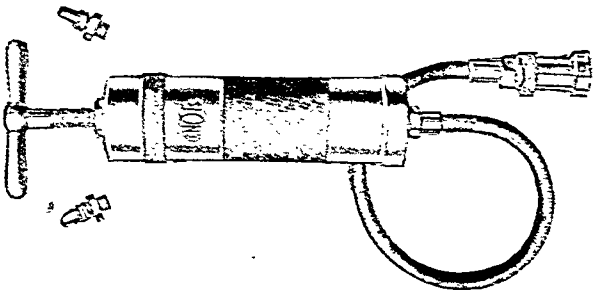
The ordinary tyre (left) made by the Associated Rubber Manufacturers, Ltd., compared with their balloon low-pressure tyre (right).

Transmission.—The accepted practice of to-day is to have fabric universal joints fitted in place of the older type of metal, and for several reasons: cheapness of replacement, absence of noise, no lubrication required, and increased flexibility when the drive is taken up, with consequent reduction of undue stresses on the engine and back axle.

Lighting and Starting Sets.

There are many types of lighting and starting sets now on the market which are simple and reliable, always providing that average attention is given them. It is essential that every doctor should have a self-starter fitted to his car. Modern self-starters are quite reliable, but they have one very vital point which the average owner gives small consideration to—that is, the battery. This is the essential part of the outfit since all current must come through it. It is also the most expensive part, and unless the plates inside are kept covered with acid or distilled water, buckled plates may result, which may cost anything from £4 to £12 to replace. If the dynamo of a modern car does not charge properly, it may be due to the slipping of the belt which drives it. If the dynamo is gear-driven and does not charge at low speeds, it should be shown to an expert. Formerly, in some small cars practically no current was generated at all at slow speeds, say at 12 miles per hour, but this may be considered a thing of the past. Whilst the car is running and the charging switch is on, the battery is being constantly filled, and when fully

FIG. 6.



Enots flexible grease gun. The smaller figures show connector valves, which replace the usual greasers.

charged the dynamo automatically cuts itself out, so that no damage can be done to the battery itself. In connexion with the efficiency of self-starters, I would point out that when starting an engine on a very cold morning it is quite useless to turn on the engine switch and press the starter button; 99 times out of 100 there is no result, and it will take about six to eight hours to make the current used during every minute that the starter button is pressed. An obvious duty the first thing in the morning is to make certain that all is ready for the electric current—that is, petrol turned on, petrol in the carburettor, air intake or inlet closed, throttle slightly open, and engine switch turned on. When these things are seen to the engine should be given two or three turns by hand before using the starter. If this is done no one need fear to go at any time in the night and find that he cannot get any light or power for starting through his accumulator having run down.

General Points for the Prospective Owner.

The cost of running a car is often exaggerated both ways; some say the expense of motoring is out of all reason, and others underestimate the cost, claiming excessively low petrol consumption and impossible life for their tyres. To arrive at a year's running cost is, of course, somewhat difficult, as luck enters into the cost to a certain degree. If the owner looks after and drives his own car, it depends largely on his knowledge of the car. If he knows sufficient and has time to carry out minor repairs, his bills will be considerably reduced. Garage is a heavy item, and difficult to obtain in towns for less than £25 to £30 per annum, and it is therefore advisable, if the necessary ground is attached to the house, for the owner to have a simple garage erected, which can be purchased from £15 upwards. In this way considerable saving can be effected after the first year.

Insurance is always advisable, owing to the danger of third party claims, and we strongly advise that a car should not be taken out until it is covered.

Registration is a heavy item, and at the present time there appears to be no hope of its being altered to a tax on petrol which; from the car-owners' point of view, would seem the most equitable method.

Chauffeurs.—If it is decided to keep a chauffeur, a careful selection will well repay the owner. It must not be considered that a chauffeur is essential. The amount of time taken to keep the outside of a car in good appearance depends to a surprising extent on its colour. Grey, for instance, requires little washing, showing little dust, and can be roughly washed, whereas blue will probably take three times the amount of work to keep it in the same condition. It has been wisely said that a doctor's car should not be blood-coloured, nor should it be shaped or painted like a hearse. If the type of lamps and equipment is studied—i.e., black plated instead of nickel—this will reduce the work to practically nil. With ordinary care and attention few repairs should be required for thousands of miles. Small adjustments can be made by the owner himself if he has studied the many excellent handbooks which are issued with each car and should present no difficulty to the average owner. In cases of electrical difficulty, it is always advisable to call in a competent firm. Many chauffeurs, of course, take the utmost pride in, and care of, cars in their charge. A good man who knows his work can save his employer many pounds per annum by doing the running adjustments or small repairs that crop up from time to time. Their wages vary very considerably in different parts of the country so that no standard figure is suggested. Giving full power to chauffeurs to order spares, &c., is not advisable as this tends to make them careless.

Second-hand Cars.—This is a difficult matter for a prospective owner to tackle, whether he be a novice or experienced motorist. It may be taken that it is a highly specialised branch, and he should place himself in the hands of a reputable firm who will advise and report on the actual car both as to price and mechanical condition.

It is difficult to deal with the many small details which crop up in connexion with the purchase of a car. If the wrong type is chosen it will lead to much disappointment and expense to the unfortunate owner. It is advisable to seek the help of a specialist who can be relied on to give unbiased advice.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Suicide Statistics.

ACCORDING to the statistical records of the Berlin police 267 cases of suicide have been registered in the first quarter of this year, the figures for the corresponding period in the last nine years being as follows: in 1915, 90; in 1916, 111; in 1917, 127; in 1918, 129; in 1919, 97; in 1920, 141; in 1921, 191; in 1922, 186; in 1923, 256. It will be seen that with the exception of 1919, the first year when there was some hope for a better future after the end of the war, the number of suicides has maintained an increase and is now nearly three times greater than in 1915. The methods of suicide have undergone certain changes in the course of time. Formerly poisoning with corrosive sublimate, with carbolic acid, lysoform, or arsenic was preferred, but the strict regulations on the sale of drugs made it more difficult to purchase such poisons, so that other means were adopted. In the majority of cases the act was committed by hanging or poisoning by gas, but many shot themselves. On the other hand, all women suicides had recourse to drowning. Poisoning by drugs has become very rare; during the first quarter of this year in six cases only was veronal, morphia, or arsenic used. The chief causes to which the suicides were ascribed were: financial ruin, incurable disease, unhappy love affairs, and melancholy. All classes of society furnish their quota, but domestic servants and workmen are in the majority.

A New Medical Society for Sports.

The interest shown in sports by a large party of the medical profession has led to the suggestion of forming a medical society for sports—not a society of medical footballers, cricketers, or tennis-players, but an association for the study of hygienic and physiological questions connected with sports. The formation of the society is backed by the large sporting and gymnastic clubs who wish to be advised as to methods of training from a medical standpoint and to have their members under medical control. Among the initiators of the scheme are several well-known professors of Berlin University, including Dr. Bier, professor of surgery, Dr. Kraus, professor of clinical medicine, Dr. Rubner, professor of hygiene, and Prof. Hueppe, formerly of Prague. A meeting has been called at which it is hoped to found the new society.

Nervousness in Children.

The German Society for School Hygiene at their annual meeting held this year in Hamburg discussed nervousness in school-children. The President, Prof. Czerny, of Berlin, stated that congenital neuropathy was not more frequent now than formerly, the increase of neurasthenia being due to external causes of which the influence of the school played a large part. Dr. Flachs, of Dresden, explained that neuropathic school-children could be divided into four types: the timid, the excited, the shy, and the apathetic. School medical officers often discover that an alleged neurasthenia is only a symptom of an organic trouble, such as epilepsy or rickets. He deprecated the exaggerated tenderness of mothers who question the children constantly on subjective symptoms, take the temperature without reason, and so spoil the child's character. "But," added Dr. Flachs, "children suffer from the bad financial condition of the parents. Sometimes they sleep too little because they must help to work. Again, the parents indulge in amusements and take the children with them. Visits to cinemas are particularly bad for children, because of the flickering and dazzle of the picture. The noise of street traffic is also very injurious. Sports are the best means of hardening the child and of strengthening its self-confidence." An argument for the Medical Society for Sports is thus furnished.

Overcrowding in the Medical Profession.

The Leipziger Verband has recently issued a further urgent warning[1] against the study of medicine, because of the overcrowding of the medical profession. They state that one of the reasons of overcrowding is that the army and navy medical corps respectively have been almost totally disbanded and consequently many members have entered civil practice and have obtained State medical appointments which were formerly the privilege of civil doctors. Another reason is that owing to the loss of the colonies and other parts of German territories many medical men from these parts have settled in the remainder of Germany. Also, the older medical men who in former times would have retired from practice at a certain age are now, through bad financial conditions, compelled to practise as long as their health permits or even until death. The Verband reminds intending medical students of the difficulties of club practice since the free choice system is in danger, so that possibly in future only a portion of the profession will have the opportunity of practising under the insurance laws. The Verband states that for many years there will be no vacancy for assistantships in hospitals and university clinics. Stress is also laid on the fact that the training of medical students is of longer duration and thus more expensive than that for other academical profession. The former warnings have already had the effect of causing a decrease in the number of medical students, but the supply still exceeds the demand. According to the *Münchener Medizinische Wochenschrift*, the number of medical students in Germany during the winter session, 1923–24, was as follows: Berlin, 1967; Munich, 1394; Leipzig, 750; Würzburg, 640; Freiburg, 588; Breslau, 572; Heidelberg, 555; Jena, 517; Bonn, 506; Kiel, 402; Marburg, 353; Frankfurt, 337; Halle, 329; Tübingen, 308; Göttingen, 307; Königsberg, 295; Greifswald, 256; Rostock, 250; Hamburg, 239; Giessen, 226; Erlangen, 209; Cologne, 168; Münster, 167. Total, 11,335.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Gastroscopy.

GASTROSCOPY has been comparatively little studied in France, and the only systematic research that was carried out by this method was done by Moure. But it is interesting to note that when Kussmal in 1886 introduced a rigid tube into the stomach for the first time he employed an endoscope which had been purchased in Paris. Since that period a great number of instruments have been invented, the best known being those of Elsner, Schindler, and Sternberg. Dr. Benschulde, physician to the hospital of St. Antoine, recently demonstrated before the Academy of Medicine a new gastroscope which he invented and which obviates some of the defects of earlier instruments. It consists of three parts: First, a tube containing the optical apparatus; secondly, a head piece, which carries a lamp and which is furnished with a guiding cannula; thirdly, a strip of steel terminating in a metal ball. In the first place the metal strip, which acts as a guiding thread, is introduced and then the gastroscope itself is slid over this strip, which passes through the cannula in the head piece. Examination is carried out in the knee-elbow position. This position has the advantage of enabling liquids to flow away from the mouth, bringing the stomach to the eye of the observer, and of freeing the cardiac end. In this position the liver falls forward against the abdominal wall and separates it from the stomach and the loops of the intestine. The view which can be obtained by the gastroscope is so clear that the greatest hope can be placed in the future of gastric endoscopy. This method, in spite of difficulties in locating points in the stomach, is one which can be of great service in the early diagnosis of cancer ulcer, rare tumours, and in certain forms of gastritis.

A Medical Club.

There are in Paris many clubs for professional and military men, but doctors possess no building where they can meet and discuss medical matters. For more than 50 years there has been a question of forming such a club, but several tentative efforts to found one have come to naught. The Association Générale de Médecins de France has taken up the idea again and has formed a committee to look into the matter. As the result of a conference held two years ago by Dr. Charles Levassort in the large theatre of the Faculty of Medicine, Dr. H. Forestier of Aix les Bains gave an account of similar organisations which existed in Copenhagen, in Stockholm, and in London, which made us regret all the more that we had no such institution. At the moment it seems as if the scheme might come to fruition. Dr. A. Thiery, president of the study committee, has made an appeal to the French Medical Corps, with the object of acquiring the old house of the University des Annales in the Place Saint Georges, which is at present vacant. It is a very fine building with a large entrance hall and many large rooms, of which one could be used as a demonstration theatre to seat 600 people. The other rooms could be used as reception rooms, lecture rooms, writing rooms, &c., or as the headquarters of various scientific and professional societies. In this way a central club might be formed, and on the premises a permanent exhibition might be held of the products of medical commercial houses. The addition of a restaurant would make the club a pleasant place in which Parisian doctors might entertain their colleagues from the provinces.

Social Aid for Abnormal Children.

The Society of Pediatrics recently held a long discussion on the question of social help for abnormal children. It was decided that the instruction of these children should not merely be optional, but ought to be enforced by law. In order to carry this into effect, it would be necessary to institute supplementary classes and to extend the system of boarding out weak-minded children who showed no moral perversity. The system would be worked from organised centres, and the children would be under the care of a doctor and a visiting nurse. It was suggested that in hospitals for children a neuro-psychiatric clinic ought to be established, the clinic to be conducted by specialists with the object of diagnosing and treating and placing abnormal children. The staff should further include a lady visitor. This department would be attached to the hospital, and would have at its disposal a certain number of beds for observation and necessary treatment. It should also work in close association with educational and boarding-out establishments, asylums, and private homes, &c.

Treatment of Delinquents in the Penal Code.

The recent congress of forensic medicine, which was held in Paris, requested the French Penal administration to institute in the Penal Code such changes as would be necessary for the physical and moral treatment and social re-education of prisoners. The congress passed a resolution in favour of developing by all possible means psychiatric and mental prophylaxis and hygiene.

---

[1] THE LANCET, March 29th, 1924, 672.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics for 1923 of two county boroughs and two boroughs, the annual health reports of which we have received :—

Name of borough.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population. All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Death-rates per 1000 births. Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Croydon C.B. ..	193,400	17·4	10·4	1·0	1·3	1·7	22	52	3·0
Southport C.B.	72,410	13·8	13·5	0·9	1·3	2·6	34	65	2·0
Swindon B. ..	55,980	17·8	9·3	1·2	1·2	1·2	32	52	0·0
Taunton B. ..	24,500	15·6	10·5	1·1	1·2	1·6	26	57	2·6

Croydon.

Dr. H. P. Newsholme compares the distribution of families at the 1921 census with that in 1911. The size of the family in 1911 was 4·28, in 1921 4·03. In 1921 19·2 per cent. of the families lived in one, two, or three rooms, as against 15·8 in 1911. The percentage of persons living in more than two to a room was 4·7 in 1921 and 4·3 in 1911. As regards constitution of the population there is at the last census a lower proportion of children under 15 owing to the declining birth-rate and a higher proportion of persons over 45, owing to the decreasing death-rate. The borough sanatorium, Cheam, is to be enlarged from 50 to 85 beds (40 for Croydon, 40 for Surrey county, and 5 for Kent county) and to be used mainly for the treatment of medium and advanced cases of pulmonary tuberculosis. The establishment of an open-air school would free beds in other institutions at present used for glandular, &c., tuberculosis for the more urgent needs of children suffering from surgical tuberculosis. Sixteen shelters are in regular use. After-care work is the least developed side of the tuberculosis scheme.

An analysis is given of the variations in infant and child mortality during 1901–21. Infant mortality has decreased to 62 per cent. of the rate of 1901–05, child mortality at the age-period 1–5 years to 66 per cent., but the mortality at the period of 5 to 15 years has remained practically constant, possibly because during this healthy period it approaches the minimum attainable. During infancy there has been no notable decrease in the fatality of bronchitis, pneumonia, premature birth, atrophy, debility, and marasmus. During early childhood there has been no notable improvement in the mortality from bronchitis, pneumonia, and measles. Midwives attend about 50 per cent. of the births, and in 1923 sent for medical help in rather less than 10 per cent. of their cases. The corporation retain 15 beds in St. Mary's (Lying-in) Hostel conducted by the Croydon Mothers' and Infants' Welfare Association, in return for an annual subsidy of £1800. Towards the end of the year it was decided to test the following allocation of the 17 beds at the hostel: 11 for normal cases, 3 for complications, 2 for emergencies, and 1 bed for isolation. Abnormal cases are attended by a rota of practitioners, each pair on duty for a week at a time, one on "first call" and the other on "second call." The usual fee paid by the Association to the practitioner is £2 per case. Arrangements are made for the six or seven pupil midwives in training at the hostel to spend the last month of their course with a Croydon midwife, with a view to gaining experience of district work. The V.D. clinic is being more used and appreciated by women patients. There is scope for more educational work in Croydon, says Dr. Newsholme, with regard to these diseases. Croydon has its housing difficulties. "It is the rule rather than the exception for the poorer class of house to be occupied by two or more families." The new houses erected during 1923 numbered 963, mostly villas for sale on completion. No municipal or other houses were completed with State assistance during 1923, but 533 houses were approved for subsidy during 1923 and up to April, 1924.

In his report as school medical officer Dr. Newsholme mentions his proposal for a rearrangement of nursing districts, by which each health visitor or nurse will be responsible for all varieties of public health nursing work within her area, including school nursing, home visiting, and centre work in connexion with maternity and child welfare, and tuberculosis visiting. Dental treatment is very incomplete at present. Only the 6–7 year-old group are inspected and of these not half accept treatment, and there is no arrangement for reinspection after 7 years of age. Dr. Newsholme submits an important scheme for extension, which involves an increase in expenditure from £700 in 1923 to about £2000 in 1926, a progressive increase in the dental staff (at present three part-time dentists conduct eight sessions weekly) to two whole-time dentists, and a corresponding increase in the nursing and clerical staff, the fuller use of the present dental clinic, and the provision, later on, of a second dental clinic, &c. By these provisions annual reinspection will be extended year by year; in due course, dental inspection will be begun at 5 years; and treatment facilities will be provided for mothers and children under 5. At the same time steps will be taken to educate the parents as to the urgency of the need for dental treatment.

A remarkably large number of cases of spinal curvature were found during routine medical inspection; 144 cases, or 2 per cent., of the children seen were referred for treatment. This prevalence was associated in some instances with the use of obsolete desks, and arrangements have been made for their steady replacement by desks of a modern type. Miss May Appleton, the organiser of physical training for girls, submits an interesting report on her work. Dr. Newsholme would welcome a similar appointment for the organisation of physical training for the boys.

Southport.

Dr. George C. Barnes appeals to the medical profession for a more careful observance of the provisions of the various Acts requiring notification. A number of births and cases of pneumonia escape notification, and about 60 per cent. of the cases of pulmonary tuberculosis are only notified in stage 3. Of the institutions subsidised by the corporation, the All Saints' creche has been closed on account of falling attendance, and the Southport Babies' Home is said to be not altogether suitable for its purpose. In the case of the latter, Dr. Barnes discusses "boarding-out" as an alternative, but thinks it would be difficult to get foster-mothers for infants. We believe, however, that the United Services Fund (Secretary, 29, Cromwell-road, S.W. 7) is able, by a system of careful selection of foster-mothers and adequate payments, to board out children of all ages successfully in country villages.

Swindon.

Dr. Dunstan Brewer reports that Swindon was exceptional in not having to face conditions of severe poverty and unemployment during 1923. The reconstruction of the sewage works is nearing completion. The first section of the storm-water scheme is almost completed, and the whole system designed to relieve the flooding of the lower part of the town will be finished ere long. The work of the storm-water scheme has abolished the long-standing nuisance caused by the canal. The nuisances caused by the condition of the public conveniences still remain to be tackled. The water shortage of the northern part of the town has been relieved by the new water main, completed in 1923. The house shortage is still acute, and "until houses in comparatively large numbers which can be *rented* are available the problem of overcrowding in Swindon is insoluble." Throughout his report Dr. Brewer continually refers to the lack of general hospital accommodation commensurate with the needs of the town, and in his conclusion he gives this and the artificial feeding of infants as the two outstanding obstacles to public health progress.

Taunton.

Dr. John Allen says, "The lack of houses of any kind is the most serious defect affecting the health of the people, while at least 700 of those in occupation are without ventilation and are quite unfit for use as dwelling-houses." Nevertheless "Health Week" was observed very actively by means of lectures, sermons, &c., and the mayor gave a prize for the best essay by an elementary school-child on "What I must do to keep healthy and fit." Dr. Allen includes in his report extracts from the Ministry's circular on cancer. In September the infant welfare centre was moved into much more convenient premises. Various brands of dried milk are stocked at the centre and sold to the mothers at cost price. Dr. Allen's opinion on its value is no uncertain one. He says, dried milk "is infinitely cleaner and has a more stable cream content than ordinary milk, and is more than equivalent to certified milk." The hours of sunshine in Taunton during 1923 were 1508·5.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 21st, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 58; scarlet fever, 1348; diphtheria, 651; enteric fever, 133 (as against 83 of the previous week); pneumonia, 708 (as against 588 of the previous week); puerperal fever, 34; cerebro-spinal fever, 9; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 161 (as against 171 of the previous week); dysentery, 6; ophthalmia neonatorum, 144 (as against 122 of the previous week). There were no cases of cholera, plague, or typhus fever notified during the week. Of the 58 cases of small-pox, 28 were notified from the county of Derby (Derby 4, Chesterfield 14, Swadlincote District 5, Chesterfield R.D. 3); 7 from Northumberland (Ashington); 6 from the county of Nottingham (Nottingham, 1, Stapleford 2); and 16 from the North Riding of Yorkshire (Middlesbrough 15). Of the cases of encephalitis lethargica 25 were reported from the county of London (Battersea 1, Bermondsey 1. Camberwell 1, Chelsea 1, Deptford 6, Finsbury 1, Hackney 1, Islington 2, Kensington 1, Lambeth 1, Poplar 1, St. Pancras 1, Shoreditch 1, Southwark 2, Stepney 3, Westminster, 1); 9 from the county of Durham (Sunderland 4, and Sunderland, R.D. 1); 5 from Essex (Walthamstow 4); 8 from the county of Gloucester (Bristol 5); 4 from Kent (Rochester 2), 22 from Lancashire (Blackburn 4, Liverpool 3, Manchester 5, Warrington 2, Accrington 2); 9 from Middlesex (Heston and Isleworth 2, Tottenham 3); 4 from Northumberland (Newcastle 3); 5 from the county of Stafford; 15 from the county of Warwick (Birmingham 9); and 12 from the West Riding of Yorks (Bradford 2, Sheffield 7).

Deaths.—In the aggregate of great towns, the deaths from influenza remained at 25, the figure for last week. The deaths from diphtheria in London fell from 14 to 8 and increased from 27 to 29 in the great towns.

HARTLEY HOSPITAL, COLNE.—This hospital, the gift of the late Sir William Hartley, of Southport, was opened on June 21st by the daughter of the donor. The total cost is estimated at £100,000. Gifts amounting to £10,000 towards the establishment of an endowment fund have been collected.

MEMORIAL TO THE LATE SIR FRANCIS FARMER.—On June 25th Mr. Asquith unveiled, at the London Hospital Medical College, a memorial to the late Sir Francis Farmer, L.D.S. R.C.S., who at the time of his death was consulting dental surgeon to the London Hospital. After paying for the tablet some £570 remain in hand from the subscriptions collected, and it is intended to use the money to establish an endowment scholarship, which will bear Sir Francis Farmer's name.

Correspondence.

"Audi alteram partem."

VOMITING AS A PATHOLOGICAL FORCE.

To the Editor of THE LANCET.

SIR,—The interesting paper by Dr. de Wesselow on the Inorganic Constituents of the Blood, which appeared in THE LANCET of May 31st (p. 1099), contains statements further supporting the view that vomiting is a pathological force. All the world recognises that vomiting at times is beneficial. Vomiting after feasts, from ancient times, has been practised—a distinguished surgeon, but a few years deceased, after attending banquets, as a routine used the stomach-tube. By unloading the overladen stomach we relieve not only that organ, but all the digestive and assimilative apparatus of a work which is excessive and causes a strain on the organs concerned, and which therefore, if too frequent in occurrence, is deleterious. And "that the vomiting of uræmia may be regarded as constituting a protective mechanism" may be admitted. It rids the body of poisons, of toxins—i.e., of natural waste products (however so changed)—it acts just in the same way as the vomiting incidental to the ingestion of such a poison, for instance, as arsenic.

Whilst this is recognised, it is not yet known that vomiting, if persistent and coercive—and quite apart from the resulting relative starvation and dehydration—has pernicious effects. I cite such states as sea-sickness, the vomiting of pregnancy, of intestinal obstruction, of uræmia. Dr. de Wesselow, under his "Table III.—Nephritis," comprising ten cases, includes one of intestinal obstruction. Referring to this case, he says: "Early in the course of obstruction, the chloride is noticeably low and the bicarbonate somewhat above the normal level; the urea retention present in this patient is a constant feature of the severer types of obstruction, and is apparently the result of definite renal damage." He then goes on to consider the findings in a case of nephritis, in which observations at four successive times were made. He says: "In Case 3, vomiting ceased shortly after the second blood sample was examined, and at the time of the third observation (28 days after the second), a more normal distribution of the acid radicles of the plasma was present. The bicarbonate was now reduced in proportion to the phosphate accumulation, and the plasma chlorides had returned to a normal level. The cessation of vomiting was accompanied by an extremely rapid gain in weight, which may have represented the restoration of the chloride and water content of the body to a normal figure, since the water content is largely determined by the amount of chlorides present in the organism."

Thus, Dr. de Wesselow, if I understand him aright, believes that by the vomiting much chloride (as HCl) is lost; and that with cessation of the vomiting this loss ceases so that the tissue cells again take up water with an increase of weight. But vomiting has not only a chemical effect; it not only rids the body of the contents of the stomach and thus affects the blood, the tissue fluids, and presumably the tissue cells: it has a mechanical effect. By vomiting, not only is the stomach compressed, but also the other abdominal organs; the liver and kidneys, with the stomach, are the subject of an impaction, or of a series of impactions—i.e., of a compression, or of a series of compressions—suddenly arising and of considerable degree. It cannot be believed that such impactions can occur without staying even for the moment the blood flow through the organs, nor can it be believed that the frequent repetition of such act is without effect on these organs, and consequently without effect on the blood. The vomiting associated with arsenical poisoning, with intestinal obstruction, with pregnancy, and we may add with sea-sickness, all result in damage to the liver and kidneys. It has been supposed that the impairment of the kidney in intestinal obstruction is due to a toxin absorbed from the obstructed gut. I have shown[1]—and according to one or two reviewers have made out a good case for my view—that the toxæmia of intestinal obstruction is not due to such a toxin, but to the effect of the persistent vomiting. We have only to consider the structure of the vascular system in the kidney and the dynamics of the blood-flow through this organ to see that undue compression of the organ must militate against its normal manner of functioning, and even to produce pathological changes. The cessation of the vomiting not only prevents further loss of water and of chlorides, it allows the blood-flow through the kidney (and through the liver) to continue undisturbed; and if the reparative powers of these viscera are normal, to cause a return to the normal state. A rapid gain in weight under such conditions is not surprising; to attribute it simply to a retention of chlorides and water is admittedly an assumption. Such conception takes no account of the relationship of the kidney function with protein—muscular—metabolism. It leaves aside altogether the question of the internal secretion of the kidney—thought by some to affect the musculature and thus to be related to body-weight—and which we may with reason suppose suffers when the other functions of the organ have bcome impaired. In short, a very important effect on the body of vomiting has been unconsidered, and until this question is settled progress cannot be made. I have urged before that man consists of so many pounds avoirdupois; that many of his vital acts are mechanically controlled. Man, in short, is a machine, in which the chemical reactions, as elsewhere in the universe, are subservient to physical conditions. To shut our eyes to the physical effects of vomiting on the body, and to see only in this act a chemical change, is to miss an essential point. It is clear the blood-flow through the viscera must be considered, and the effects of acts such as vomiting on this be determined.

I am, Sir, yours faithfully,

Rugby, June 15th, 1924. R. H. Paramore.

THE SCHICK TEST.

To the Editor of The Lancet.

Sir,—May I comment on a few points in the valuable record of observations on the Schick test by Dr. C. B. Ker and Dr. J. McGarrity in your issue of May 31st. We agree with what Dr. Ker finds—i.e., that a "positive and pseudo" reactor can be immunised successfully so that he later becomes a "negative and pseudo" reactor. The mistake referred to in Dr. Ker's letter of June 28th has probably arisen from my careless use of the clumsy terms relating to these two classes of people. In laboratory jargon we speak of a "negative and pseudo" reactor as a "pseudo" reactor, and I have probably unintentionally misled Dr. Ker as to our opinion by saying that a "pseudo" reactor (meaning a "negative and pseudo" reactor) is immune and does not need prophylactic.

The authors quote laboratory work as showing that all antitoxin may have disappeared from the blood in 12 days. I should think this is an unusually short period, though we have recently obtained a clear positive Schick reaction in an adult who received a dose (probably 500 units) of antitoxin 14 days previously. We are at present engaged in examining the blood from a number of patients at various intervals after receipt of diphtheria antitoxin, and we find that the majority of these patients have a small but detectable amount of antitoxin in their blood four to five weeks after the injection of antitoxin. Most of these patients retained so little antitoxin that they would probably have given a positive Schick reaction. We think the laboratory evidence agrees with what Dr. Ker finds from his wide clinical experience—i.e., that a dose of antitoxin gives protection for three weeks. It would be interesting to know whether the nurse who gave a slight reaction on both arms and after being classed as negative developed diphtheria, had a severe or mild attack. We have records of three patients in four years' work who had certainly given a Schick negative reaction, and later on suffered from a sore-throat and yielded virulent K.L.B. in culture. All three patients showed very slight symptoms, and may justifiably be classed with what Dr. Harries calls "a transient tonsillitis associated with the presence of morphological diphtheria bacilli."

Dr. Ker and Dr. McGarrity did not find the reading at 24 hours accurate in a very high percentage of instances. The delay in the appearance of the reaction amongst their patients may be connected with the ill-health of the children. My colleague, Mr. Glenny, finds that in ill- or badly-nourished guinea-pigs the reactions are reduced in intensity and may be delayed. The children quoted in our papers were almost all healthy children, inmates of schools or institutions. We have not had many opportunities recently of making 24-hour readings on large numbers of children, but our evidence in the past year or two confirms the expectation derived from our earlier work that approximately 95 per cent. of *healthy* children will give over-night reactions that agree with later readings.

In view of Dr. Ker's experience, it is evident that further attention must be given to this important point in the future.

I am, Sir, yours faithfully,

R. A. O'Brien.

Wellcome Physiological Research Laboratories,
Beckenham, June 30th, 1924.

THE FORBES FRASER MEMORIAL FUND.

To the Editor of The Lancet.

Sir,—In view of the generally expressed wish that there should be some lasting memorial to the life and work of the late Mr. Forbes Fraser, a small committee, with the Mayor of Bath as chairman, has been formed to consider how best to give effect to this widespread desire. The medical men on the committee include Dr. C. E. S. Flemming, Dr. F. G. Thomson, and Mr. W. G. Mumford. It is felt by the committee that whatever form the memorial takes it should be in some way connected with the recently opened hospital at Combe Park, the inception of which was mainly due to Mr. Forbes Fraser. Not only did the idea originate with him, but it was largely owing to his stimulating influence and untiring energy that the difficulties connected with the building and equipment of the hospital have eventually been overcome. In order to commemorate his work, the hospital committee have decided that the institution shall in future be known as the Forbes Fraser Hospital.

Owing to the limited funds available, it has been found impossible to provide the Forbes Fraser Hospital with certain very necessary equipment. One of the most pressing needs is the provision of a thoroughly well equipped X ray department. Mr. Fraser was himself urgently impressed with this need, and at the time of his illness was actually considering plans for its provision. It is felt by the committee that no fitter memorial to his memory could be devised than to provide the funds necessary to instal this department.

The total cost of the erection and equipment of an X ray department is estimated at from £2500 to £3000; donations may be sent to Mrs. A. L. Hope, Eagle House, Bathford, Somerset, or may be paid direct to the Forbes Fraser Memorial Fund, National Provincial Bank, High-street, Bath.

I am, Sir, yours faithfully,

A. L. Hope,
Hon. Secretary and Treasurer, Forbes Fraser Memorial Fund.

June 28th, 1924.

SPINAL ANALGESIA.

To the Editor of THE LANCET.

SIR,—Mr. Holroyd [illegible] in his paper on this subject in THE LANCET of June 21st, says with regard to disadvantages of this method of anæsthesia, "I know of none, provided the technique be correct, save the slight extra work which devolves on the surgeon." May I remind him of a complication which certainly is not common, but which I happen to have seen twice lately, and that is paralysis of one or other sixth cranial nerve. It is by no means a trivial complication, and the resulting diplopia is most confusing and distressing to the patient.

I am, Sir, yours faithfully,
R. FOSTER MOORE.
Harley-street, W., July 1st, 1924.

OSTEOPATHY IN ITS MEDICO-LEGAL ASPECTS: A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In your report in THE LANCET of June 28th of the meeting of the Medico-Legal Society, at which Dr. Norman J. Macdonald read a paper on this subject, I am credited with certain remarks in the subsequent discussion of the paper. As a matter of fact, though I am a member of the Medico-Legal Society, I was not present at this particular meeting. As the remarks attributed to me by no means represent my views on the subject, I should be much obliged if you would publish this letter, disclaiming them.

I am, Sir, yours faithfully,
ARTHUR S. MORLEY.
Gordon-square, W.C., June 27th, 1924.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

To be Surg. Lts.: J. H. Laydon, J. J. O'Reilly, and J. J. A. O'Sullivan.

ROYAL NAVAL VOLUNTEER RESERVE.

T. W. Drummond, late Temp. Surg. Lt. R.N., to be Surg. Lt. R.N.V.R.

ROYAL ARMY MEDICAL CORPS.

Temp. Capts. H. H. Crickitt and R. B. Hunt (on account of ill-health) relinquish their commns. and retain the rank of Capt.

MILITIA.

Capt. A. E. B. Paul relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. I. M. Pirrie (late R.A.M.C., Militia) to be Capt.

ROYAL AIR FORCE.

Flying Officer V. S. Ewing is promoted to the rank of Flight Lt.

DONATIONS AND BEQUESTS.—Following on the death of Mrs. Mellor the trustees under the will of the late Colonel John James Mellor, of Manchester, who was Member of Parliament for the Radcliffe-cum-Farnworth Division, have made a partial distribution of his charitable bequests, including £1000 each to the Manchester Royal Infirmary, Bury Infirmary, Christie Cancer Hospital, St. Mary's Hospitals for Women and Children, Manchester, and the Children's Hospital, Pendlebury, Manchester, to endow a "Mellor" bed in each institution; also £2500 to found a Mellor Nursing Fund for the provision of a nurse for Whitefield; £1000 to the existing Mellor Convalescent Fund; £1000 for Lytham Cottage Hospital; and £500 to the Manchester and District Surgical Aid Society.—The late Mr. Frederick William Smith, of Ramsgate, left by will £500 to the General Hospital, Monmouth, for a bed to be known as the "Maria Smith Bed," in memory of his mother. Part of the residue of the property he left to the Seamen's Infirmary, Ramsgate, on the death of his wife.

Medical News.

UNIVERSITY OF GLASGOW.—At the graduation ceremony on June [illegible], degrees were conferred as follows:—

Hon. LL.D.—Sir Malcolm Watson, Senior [illegible], Federated Malay States Medical Service.

M.D. (with Honours).—David Campbell, M.A., B.Sc., M.B., Ch.B. (Thesis: Studies on the Rheumatic [illegible] and its Treatment, with special reference to the use of Non-specific [illegible]); [illegible] Gillespie, M.B., Ch.B. (Thesis: The [illegible] Basis of Clinical Tests of Cardiac Efficiency).—*In Absentia.*

D.Sc.—James H. [illegible], M.A., B.Sc., M.B., Ch.B. (Thesis: Studies in Special [illegible] Physiology.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the Primary Fellowship Examination held from June [illegible] to [illegible], for which [illegible] candidates presented themselves, [illegible] were approved and [illegible] were rejected. The successful candidates were as follows:—

J. L. [illegible], Liverpool; [illegible]; [illegible], Cambridge and St. Bart.'s; G. M. J. [illegible], Otago and Middlesex; F. G. [illegible], Cambridge and Middlesex; [illegible] and A. [illegible], St. Thomas's; F. L. [illegible], King's Coll. and St. Mary's; H. J. [illegible], Cambridge and St. Bart.'s; J. E. [illegible], St. Bart.'s; J. L. [illegible], Melbourne and Middlesex; S. W. [illegible], Manchester; [illegible], Oxford and St. Thomas's; [illegible], Manchester and St. Mary's; R. A. [illegible], Middlesex; W. A. Gray, Edinburgh and St. Mary's; P. [illegible], Guy's; [illegible], Sydney and Middlesex; R. P. S. [illegible], Otago; [illegible] Lloyd, Guy's; E. E. Mackay, Melbourne and Middlesex; J. McMichael, Edinburgh and St. Bart.'s; [illegible], Edinburgh and St. Mary's; F. W. G. [illegible], Middlesex; C. H. Osborn, Melbourne and Middlesex; C. L. [illegible], Cambridge; A. M. Reid, Liverpool and Middlesex; J. Roberts, Liverpool; M. P. [illegible], Sydney and Middlesex; S. N. Taylor, Manchester and St. Mary's; and C. L. [illegible], St. Mary's and Middlesex.

ROYAL COLLEGE OF SURGEONS IN IRELAND: *Election of Examiners.*—At a meeting held on June [illegible], Mr. Robert C. B. Maunsell, President, in the chair, the following were elected as examiners for the ensuing year:—

Court "A" (Conjoint Licence, Diploma in Public Health, and Preliminary).—Anatomy: Prof. E. J. Evatt. Surgery: Mr. L. G. Gunn and Prof. G. J. Johnston. Physiology and Histology: Prof. J. A. Scott. Pathology and Bacteriology: Prof. W. Boxwell. Midwifery and Gynæcology: [illegible] E. H. Tweedy. Biology: Prof. [illegible]. Ophthalmology: F. C. Crawley and R. D. Joyce. Chemistry and Physics: Prof. W. Caldwell. Chemistry and Physics, for Diploma in Public Health only: Prof. W. Caldwell and Dr. S. Young. Materia Medica, Pharmacy, and Therapeutics: Prof. R. J. Rowlette. Forensic Medicine and Public Health: Prof. V. M. Synge.

Court "B" (Fellowship, Licence in Dental Surgery).—Anatomy: Prof. E. J. Evatt and Dr. C. M. West. Surgery: Mr. [illegible] Chance, Mr. L. G. Gunn, Prof. G. J. Johnston, and Mr. H. Stokes. Physiology and Histology: Prof. [illegible] and Prof. J. A. Scott. Pathology and Bacteriology: Prof. W. Boxwell and Prof. R. J. Rowlette. Chemistry and Physics: Prof. W. Caldwell and Dr. S. Young. Dental Surgery and Pathology: Mr. G. Sheppard and Mr. [illegible] Doolin. Mechanical Dentistry: Mr. [illegible] and Mr. J. Cockburn.

AUGUSTUS AND ALICE WALLER MEMORIAL.—A meeting of subscribers to the fund which has been raised in memory of the late Dr. and Mrs. Augustus D. Waller is to be held at the London (R.F.H.) School of Medicine for Women, on Thursday, July 17th, at 5 P.M. Sir Edward Sharpey Schafer will preside. In inviting contributions the organising committee stated that the Memorial should take the form of a fund for the encouragement of [illegible] Research to be administered by the Council of the London (R.F.H.) School of Medicine for Women, and the final arrangements concerning the Memorial will be decided at the meeting. Intending subscribers [illegible] subscriptions to the Hon. Treasurer, [illegible], St. Thomas's Hospital Medical School, [illegible] possible. £1820 have been subscribed, and [illegible] the total of £2000 will be reached.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on June [illegible], [illegible] Professor of [illegible] University College, [illegible] was adopted. [illegible] in the University was [illegible] in respect of his appointment [illegible] Surgical Unit at University College Hospital Medical School. The title of Professor of Physics kidneys. It has been supposed that the impairment of the kidney in intestinal obstruction is due to a toxin absorbed from the obstructed gut. I have shown[1]—and according to one or two reviewers have made out a good case for my view—that the toxæmia of intestinal obstruction is not due to such a toxin, but to the effect of the persistent vomiting. We have only to consider the structure of the vascular system in the kidney and the dynamics of the blood-flow through this organ to see that undue compression of the organ must militate against its normal manner of functioning, and even to produce pathological changes. The cessation of the vomiting not only prevents further loss of water and of chlorides, it allows the blood-flow through the kidney (and through the liver) to continue undisturbed; and if the reparative powers of these viscera are normal, to cause a return to the normal state. A rapid gain in weight under such conditions is not surprising; to attribute it simply to a retention of chlorides and water is admittedly an assumption. Such conception takes no account of the relationship of the kidney function with protein—muscular—metabolism. It leaves aside altogether the question of the internal secretion of the kidney—thought by some to affect the musculature and thus to be related to body-weight—and which we may with reason suppose suffers when the other functions of the organ have bcome impaired. In short, a very important effect on the body of vomiting has been unconsidered, and until this question is settled progress cannot be made. I have urged before that man consists of so many pounds avoirdupois; that many of his vital acts are mechanically controlled. Man, in short, is a machine, in which the chemical reactions, as elsewhere in the universe, are subservient to physical conditions. To shut our eyes to the physical effects of vomiting on the body, and to see only in this act a chemical change, is to miss an essential point. It is clear the blood-flow through the viscera must be considered, and the effects of acts such as vomiting on this be determined.

I am, Sir, yours faithfully,

Rugby, June 15th, 1924. R. H. Paramore.

THE SCHICK TEST.

To the Editor of The Lancet.

Sir,—May I comment on a few points in the valuable record of observations on the Schick test by Dr. C. B. Ker and Dr. J. McGarrity in your issue of May 31st. We agree with what Dr. Ker finds—i.e., that a "positive and pseudo" reactor can be immunised successfully so that he later becomes a "negative and pseudo" reactor. The mistake referred to in Dr. Ker's letter of June 28th has probably arisen from my careless use of the clumsy terms relating to these two classes of people. In laboratory jargon we speak of a "negative and pseudo" reactor as a "pseudo" reactor, and I have probably unintentionally misled Dr. Ker as to our opinion by saying that a "pseudo" reactor (meaning a "negative and pseudo" reactor) is immune and does not need prophylactic.

The authors quote laboratory work as showing that all antitoxin may have disappeared from the blood in 12 days. I should think this is an unusually short period, though we have recently obtained a clear positive Schick reaction in an adult who received a dose (probably 500 units) of antitoxin 14 days previously. We are at present engaged in examining the blood from a number of patients at various intervals after receipt of diphtheria antitoxin, and we find that the majority of these patients have a small but detectable amount of antitoxin in their blood four to five weeks after the injection of antitoxin. Most of these patients retained so little antitoxin that they would probably have given a positive Schick reaction. We think the laboratory evidence agrees with what Dr. Ker finds from his wide clinical experience—i.e., that a dose of antitoxin gives protection for three weeks. It would be interesting to know whether the nurse who gave a slight reaction on both arms and after being classed as negative developed diphtheria, had a severe or mild attack. We have records of three patients in four years' work who had certainly given a Schick negative reaction, and later on suffered from a sore-throat and yielded virulent K.L.B. in culture. All three patients showed very slight symptoms, and may justifiably be classed with what Dr. Harries calls "a transient tonsillitis associated with the presence of morphological diphtheria bacilli."

Dr. Ker and Dr. McGarrity did not find the reading at 24 hours accurate in a very high percentage of instances. The delay in the appearance of the reaction amongst their patients may be connected with the ill-health of the children. My colleague, Mr. Glenny, finds that in ill- or badly-nourished guinea-pigs the reactions are reduced in intensity and may be delayed. The children quoted in our papers were almost all healthy children, inmates of schools or institutions. We have not had many opportunities recently of making 24-hour readings on large numbers of children, but our evidence in the past year or two confirms the expectation derived from our earlier work that approximately 95 per cent. of *healthy* children will give over-night reactions that agree with later readings.

In view of Dr. Ker's experience, it is evident that further attention must be given to this important point in the future.

I am, Sir, yours faithfully,

R. A. O'Brien.

Wellcome Physiological Research Laboratories,
Beckenham, June 30th, 1924.

THE FORBES FRASER MEMORIAL FUND.

To the Editor of The Lancet.

Sir,—In view of the generally expressed wish that there should be some lasting memorial to the life and work of the late Mr. Forbes Fraser, a small committee, with the Mayor of Bath as chairman, has been formed to consider how best to give effect to this widespread desire. The medical men on the committee include Dr. C. E. S. Flemming, Dr. F. G. Thomson, and Mr. W. G. Mumford. It is felt by the committee that whatever form the memorial takes it should be in some way connected with the recently opened hospital at Combe Park, the inception of which was mainly due to Mr. Forbes Fraser. Not only did the idea originate with him, but it was largely owing to his stimulating influence and untiring energy that the difficulties connected with the building and equipment of the hospital have eventually been overcome. In order to commemorate his work, the hospital committee have decided that the institution shall in future be known as the Forbes Fraser Hospital.

Owing to the limited funds available, it has been found impossible to provide the Forbes Fraser Hospital with certain very necessary equipment. One of the most pressing needs is the provision of a thoroughly well equipped X ray department. Mr. Fraser was himself urgently impressed with this need, and at the time of his illness was actually considering plans for its provision. It is felt by the committee that no fitter memorial to his memory could be devised than to provide the funds necessary to instal this department.

The total cost of the erection and equipment of an X ray department is estimated at from £2500 to £3000; donations may be sent to Mrs. A. L. Hope, Eagle House, Bathford, Somerset, or may be paid direct to the Forbes Fraser Memorial Fund, National Provincial Bank, High-street, Bath.

I am, Sir, yours faithfully,

A. L. Hope,
Hon. Secretary and Treasurer, Forbes Fraser Memorial Fund.

June 28th, 1924.

SPINAL ANALGESIA.

To the Editor of THE LANCET.

SIR,—Mr. Holroyd Slater, in his paper on this subject in THE LANCET of June 21st, says with regard to disadvantages of this method of anæsthesia, "I know of none, provided the technique be correct, save the slight extra work which devolves on the surgeon." May I remind him of a complication which certainly is not common, but which I happen to have seen twice lately, and that is paralysis of one or other sixth cranial nerve. It is by no means a trivial complication, and the resulting diplopia is most confusing and distressing to the patient.

I am, Sir, yours faithfully,
R. FOSTER MOORE.

Harley-street, W., July 1st, 1924.

OSTEOPATHY IN ITS MEDICO-LEGAL ASPECTS: A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In your report in THE LANCET of June 28th of the meeting of the Medico-Legal Society, at which Dr. Norman J. Macdonald read a paper on this subject, I am credited with certain remarks in the subsequent discussion of the paper. As a matter of fact, though I am a member of the Medico-Legal Society, I was not present at this particular meeting. As the remarks attributed to me by no means represent my views on the subject, I should be much obliged if you would publish this letter, disclaiming them.

I am, Sir, yours faithfully,
ARTHUR S. MORLEY.

Gordon-square, W.C., June 27th, 1924.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

To be Surg. Lts.: J. H. Laydon, J. J. O'Reilly, and J. J. A. O'Sullivan.

ROYAL NAVAL VOLUNTEER RESERVE.

T. W. Drummond, late Temp. Surg. Lt. R.N., to be Surg. Lt. R.N.V.R.

ROYAL ARMY MEDICAL CORPS.

Temp. Capts. H. H. Crickitt and R. B. Hunt (on account of ill-health) relinquish their commns. and retain the rank of Capt.

MILITIA.

Capt. A. E. B. Paul relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. I. M. Pirrie (late R.A.M.C., Militia) to be Capt.

ROYAL AIR FORCE.

Flying Officer V. S. Ewing is promoted to the rank of Flight Lt.

DONATIONS AND BEQUESTS.—Following on the death of Mrs. Mellor the trustees under the will of the late Colonel John James Mellor, of Manchester, who was Member of Parliament for the Radcliffe-cum-Farnworth Division, have made a partial distribution of his charitable bequests, including £1000 each to the Manchester Royal Infirmary, Bury Infirmary, Christie Cancer Hospital, St. Mary's Hospitals for Women and Children, Manchester, and the Children's Hospital, Pendlebury, Manchester, to endow a "Mellor" bed in each institution; also £2500 to found a Mellor Nursing Fund for the provision of a nurse for Whitefield; £1000 to the existing Mellor Convalescent Fund; £1000 for Lytham Cottage Hospital; and £500 to the Manchester and District Surgical Aid Society.—The late Mr. Frederick William Smith, of Ramsgate, left by will £500 to the General Hospital, Monmouth, for a bed to be known as the "Maria Smith Bed," in memory of his mother. Part of the residue of the property he left to the Seamen's Infirmary, Ramsgate, on the death of his wife.

Medical News.

UNIVERSITY OF GLASGOW.—At the graduation ceremony on June 25th, degrees were conferred as follows:—

Hon. LL.D.—Sir Malcolm Watson (Senior District Surgeon, Federated Malay States Medical Service).

M.D. (With Honours).—David Campbell, M.A., B.Sc., M.B., Ch.B. (Thesis: Studies on (1) Rheumatoid Arthritis and its Treatment, with special reference to the use of Non-Specific Protein Reaction; (2) Ionic Medication.) Robert D. Gillespie, M.B., Ch.B. (Thesis: The Physiological Basis of Clinical Tests of Cardiac Efficiency.)—*In Absentia.*

D.Sc.—James H. Paul, M.A., B.Sc., M.B., Ch.B. (Thesis: Studies in Special Crustacean Physiology.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the Primary Fellowship Examination held from June 10th to 18th, for which 100 candidates presented themselves, 31 were approved and 69 were rejected. The successful candidates were as follows:—

J. L. Armour, Liverpool; Alfreda Helen Baker, Belfast; H. Barbash, Cambridge and St. Bart.'s; G. M. F. Barnett, Otago and Middlesex; P. G. Bentlif, Cambridge and Middlesex; R. H. Boggon and A. Byrne-Quinn, St. Thomas's; F. A. Bryning, King's Coll. and St. Mary's; H. J. Burrows, Cambridge and St. Bart.'s; J. B. Crabtree, St. Bart.'s; J. L. Diggle, Melbourne and Middlesex; S. W. Drinkwater, Manchester; V. T. Ellwood, Oxford and St. Thomas's; E. S. Frischmann, Manchester and St. Mary's; R. A. Graff, Middlesex; W. A. Gray, Edinburgh and St. Mary's; P. Hack, Guy's; J. A. James, Sydney and Middlesex; R. P. S. Kelman, Otago; V. E. Lloyd, Guy's; E. E. Mackay, Melbourne and Middlesex; J. McMichael, Edinburgh and St. Bart.'s; D. S. Middleton, Edinburgh and St. Mary's; F. W. G. Nash, Middlesex; C. H. Osborn, Melbourne and Middlesex; C. L. Owen, Cambridge; A. M. Reid, Liverpool and Middlesex; J. Roberts, Liverpool; M. P. Susman, Sydney and Middlesex; S. N. Taylor, Manchester and St. Mary's; and C. I. Tuckett, St. Mary's and Middlesex.

ROYAL COLLEGE OF SURGEONS IN IRELAND: *Election of Examiners.*—At a meeting held on June 19th, Mr. Robert C. B. Maunsell, President, in the chair, the following were elected as examiners for the ensuing year:—

Court "A" (Conjoint Licence, Diploma in Public Health, and Preliminary).—Anatomy: Prof. E. J. Evatt. Surgery: Mr. L. G. Gunn and Prof. G. J. Johnston. Physiology and Histology: Prof. J. A. Scott. Pathology and Bacteriology: Prof. W. Boxwell. Midwifery and Gynæcology: Prof. E. H. Tweedy. Biology: Prof. MacD. Cosgrave. Ophthalmology: F. C. Crawley and R. D. Joyce. Chemistry and Physics: Prof. W. Caldwell. Chemistry and Physics, for Diploma in Public Health only: Prof. W. Caldwell and Dr. S. Young. Materia Medica, Pharmacy, and Therapeutics: Prof. R. J. Rowlette. Forensic Medicine and Public Health: Prof. V. M. Synge.

Court "B" (Fellowship, Licence in Dental Surgery).—Anatomy: Prof. E. J. Evatt and Dr. C. M. West. Surgery: Mr. A. Chance, Mr. L. G. Gunn, Prof. G. J. Johnston, and Mr. H. Stokes. Physiology and Histology: Prof. F. C. Purser and Prof. J. A. Scott. Pathology and Bacteriology: Prof. W. Boxwell and Prof. R. J. Rowlette. Chemistry and Physics: Prof. W. Caldwell and Dr. S. Young. Dental Surgery and Pathology: Mr. G. Sheppard and Mr. D. Doolin. Mechanical Dentistry: Mr. D. L. Rogers and Mr. J. Cockburn.

AUGUSTUS AND ALICE WALLER MEMORIAL.—A meeting of subscribers to the fund which has been raised in memory of the late Dr. and Mrs. Augustus D. Waller is to be held at the London (R.F.H.) School of Medicine for Women, on Thursday, July 17th, at 5 P.M. Sir Edward Sharpey Schafer will preside. In inviting contributions the organising committee stated that the Memorial should take the form of a fund for the encouragement of Scientific Research to be administered by the Council of the London (R.F.H.) School of Medicine for Women, and the final arrangements concerning the Memorial will be decided at the meeting. Intending subscribers are asked to send their subscriptions to the Hon. Treasurer, Prof. John Mellanby, St. Thomas's Hospital Medical School, S.E. 1, as soon as possible. £1820 have been subscribed, and it is hoped that the total of £2000 will be reached.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on June 25th, Prof. E. A. Gardner, Yates Professor of Archæology in the University, tenable at University College, was elected Vice-Chancellor for 1924–25 in succession to Mr. H. J. Waring. A cordial vote of thanks was passed to Mr. Waring for the services which he had rendered to the University during his term of office as Vice-Chancellor.—A vote of condolence on the death of Dr. R. M. Walmsley, Chairman of Convocation, was adopted. —The title of Professor of Surgery in the University was conferred on Mr. C. C. Choyce, in respect of his appointment as Director of the Surgical Unit at University College Hospital Medical School.—The title of Professor of Physics in the University was conferred on Prof. O. W. Richardson, F.R.S., in respect of his part-time appointment as Director of Research in the Department of Physics at King's College. Prof. Richardson will cease to hold the Wheatstone Chair of Physics, which he has occupied since 1914, on taking up the Yarrow Research Professorship of the Royal Society on August 1st next.—Nine grants were made out of the Dixon Fund for the year 1924–25 for researches, among which were the following, to be carried out at the College or Institution designated:—To William E. Downey the sum of £50 for (*a*) the spectroscopic study of luminescences and flames, more particularly that of phosphorus; (*b*) the relation between chemical action and light emission. (Imp. Coll., R.C.S.) To Violet M. Grubb the sum of £20 for the continuation of investigation into the structure and reproduction of certain red and green algæ (more particularly the delimitation of species in *Cladophora* and *Gelidium*, and the investigation of spermatial stages in the *Florideæ*). (Botanical Laboratory, Westfield College.) To Alan S. Parkes the sum of £50 for research on the physiological factors governing the proportions of the sexes in mammals, with the object of finding some means whereby the proportions may be controlled. (Institute of Physiology, University College.) To Eric A. Spaul the sum of £50 to continue experiments with the anterior lobe pituitary gland, and to gain further knowledge of the properties of the active principles of this portion of the gland, and also its biochemical properties. (Zoological Laboratory, Birkbeck College.) To Florence M. Wood the sum of £50 for chemicals and apparatus in connexion with research upon the chemical nature of the cellulose membrane. (Probably Birkbeck College.) To Muriel Bond the sum of £20 for research on "The Dietetic Factors Influencing Reproduction." (Physiological Laboratory, London School of Medicine for Women.)

The following doctorates were conferred:—D.Lit.: C. Delisle Burns (London School of Economics) for a thesis entitled "Psychological Data and Moral Standards in Contemporary Industry." D.Sc. in Physiology: J. A. Hewitt (King's College) for a thesis entitled "Metabolism of Carbohydrates (Part III.)." D.Sc. in Physiology: F. M. R. Walshe (University College and University College Hospital Medical School) for a thesis entitled "(i.) The Physiological Significance of the Reflex Phenomena in Spastic Paralysis of the Lower Limbs; (ii.) On Certain Tonic or Postural Reflexes in Man, with Special Reference to the so-called 'Associated Movements'; (iii.) On Variations in the Form of Reflex Movements, notably the Babinski Plantar response, under Different Degrees of Spasticity and Under the Influence of Magnus and de Kleijn's Tonic Neck Reflex."

Prof. H. R. Kenwood was appointed representative (in respect of University College) at the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis to be held in London in July, 1924.—The Maudsley Hospital has been admitted as a School of the University in the Faculty of Medicine for the purpose of research in psychological medicine.

Society for the Prevention of Venereal Disease.—The fifth annual general meeting of the society will take place at the Adam Hall, 12, Stratford-place, London, W., on Thursday, July 10th, at 5.30 P.M., when the President, Sir Auckland Geddes, will deliver his first presidential address. Dr. J. H. Sequeira, Lady Askwith, Captain Walter Elliot, M.P., and Mr. H. Wansey Bayly will also speak.

Diplomas in Psychological Medicine. — The Universities of Cambridge, London, Durham, Leeds, Manchester, and Edinburgh, and the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England now grant Diplomas in Psychological Medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses. Details can be obtained from the various examination bodies. In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been recognised as a school of the University of London. The course consists of two parts, and is adapted for the Diploma of the Conjoint Board, the University of London, or the University of Cambridge, Part I. being conducted by Sir Frederick Mott, Dr. F. Golla, and Dr. Henry Devine, and Part II. by Sir Frederick Mott, Dr. Bernard Hart, Dr. Golla, Dr. F. C. Shrubsall, Dr. W. C. Sullivan, Dr. C. Hubert Bond, and Dr. E. Mapother. Appointments as clinical assistants are obtainable at the hospital, and the holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. Further particulars as to the lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5, and as to clinical facilities to the medical superintendent of the hospital.

Durham University Medical Graduates' Association.—At the annual general meeting of the association, held on June 26th, the following were elected officers for the year 1924–25:—President: Dr. G. de B. Turtle. Vice-Presidents: Dr. A. Parkin and Mr. C. W. Hope. Hon. Secretaries for North and South: Dr. S. W. Davidson and Dr. F. W. M. Pratt respectively. Hon. Treasurer: Dr. W. D. Forrest.

British Association.—The annual meeting of the British Association for the Advancement of Science to be held in Toronto in August will be under the presidency of Major-General Sir David Bruce. The President will deliver the opening address on August 6th on the Prevention of Disease, and will deal with the experience in this field gained during the war. Five hundred members of the Association will travel to Canada for the meeting, which will begin on August 7th and continue until August 13th. The sectional presidential addresses will include discourses on Chemistry and the State, by Sir Robert Robertson; Inter-Racial Problems and White Colonisation in the Tropics, by Prof. J. W. Gregory; and Academic Freedom in Universities, by Principal Ernest Barker.

Royal Sanitary Institute. — The Thirty-fifth Congress of the Royal Sanitary Institute will be held at Liverpool from July 14th to 19th under the presidency of Lord Salisbury. The Congress will consist of 11 sections, and will deal with many aspects of hygiene, in particular maternity and child welfare, public health education, and the value of voluntary public health work. Food and feeding in their several aspects, including milk in its production and also water-supply, will come under discussion. There is a Conference specially devoted to port sanitary authorities, in which ship sanitation will be discussed. As a practical demonstration of many of the subjects, a large health exhibition is held in connexion with the meeting. Among those who will preside over the different sections are Lieut.-General Sir William Leishman, Dr. T. M. Legge, Dr. E. W. Hope, and Dr. T. W. Naylor Barlow. A large attendance is expected, which will consist mainly of officers and representatives of Government departments, municipal and public health departments in the United Kingdom, and including also many representatives of foreign Governments, dominions, and colonies of the Empire. On July 16th Prof. H. R. Kenwood, of London University, will deliver a popular lecture on Modern Civilisation from the Health Standpoint. Full particulars of the Congress may be obtained from the secretary at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. 1.

The late Dr. C. Burland.—Dr. Charles Burland, formerly senior medical officer to the Marine Department of the Board of Trade, who died on June 29th at his residence in Southampton at the age of 63, was the eldest son of the late Rev. C. I. Burland, vicar of St. Saviour's, Shanklin. He received his early education on H.M.S. *Conway*, and at Yorkshire College, Leeds, and proceeded to the study of medicine at the University of Edinburgh and in Paris. He qualified L.R.C.P., L.R.C.S. Edin. in 1881, and in 1890 graduated with honours M.D. Brussels. During the South African war he was appointed to the medical charge of invalid troops, and obtained for his services the medal with clasp; later he served as surgeon to the P. and O. and Cunard steamship lines. In 1906 he was appointed Board of Trade medical inspector in Glasgow and for the Western District of Scotland, and in 1909 senior medical officer and Government medical inspector of emigration at the port of Liverpool. Two years later he became chairman of the Advisory Committee on Medical Equipment of Merchant Ships. He was an ex-president of the Brussels Medical Graduates' Association. Dr. Burland contributed several papers to The Lancet dealing with points in the treatment of symptomatology of various disease conditions. He was also the author of the well-known "Ship Captain's Medical Guide," published by the Board of Trade, which has gone through 16 editions, and in 1919 he composed the official leaflet on How to Keep Clear of Influenza.

Maternal Mortality. — In a circular letter (No. 517. H.M. Stationery Office. 1*d.*) dated June 30th, addressed to local authorities, the Minister of Health calls special attention to various suggestions for the prevention and remedy of the present high rate of maternal mortality, made by Dr. Janet Campbell in her recent report on this subject, which was discussed in The Lancet dated April 5th (p. 716) and 19th (p. 809). Of these suggestions adequate provision for antenatal supervision is regarded as of primary importance. Antenatal supervision may be given partly through the doctor or midwife engaged by the patient, but also by means of maternity centres established by the local authority.

There are now in this country some 560 antenatal centres, and there is a need for many more. The provision of maternity beds for the institutional treatment of complicated midwifery cases and for women whose homes are unfit for a confinement to take place therein is another essential part of any scheme designed to lower maternal mortality. As to domestic midwifery and maternity nursing, the Minister holds that maternity nursing by trained midwives should be encouraged whether a doctor is engaged or not, and the employment of unqualified "maternity nurses" should be controlled as far as practicable. The searching investigation of all maternal deaths, of cases of puerperal fever, and of stillbirths and neonatal deaths is regarded as desirable, and educational measures are urged in order that an informed and enlightened public opinion in regard to maternal mortality may be created. The Minister suggests, in conclusion, that medical officers of health should be instructed to report upon the steps considered necessary to provide an efficient maternity service in each area, and he announces his readiness to consider any proposals of the local authority for this purpose which may be submitted for his approval under the Maternity and Child Welfare Act, 1918.

INSULIN: REDUCED PRICES.—The second reading of the Public Health (Scotland) Bill, designed to enable local authorities in Scotland to assist diabetics unable to afford insulin to obtain this remedy, was passed by the House of Commons on July 1st. The reduction in the price of insulin is proceeding so rapidly that legislation may soon be unnecessary. The first insulin made in this country a little over 12 months ago cost 25*s.* for 10 doses. Messrs. Burroughs and Wellcome now inform us that following improved manufacturing methods carried out in their laboratories, they are able to announce a fifth reduction in the price of "Wellcome" Brand Insulin. The British Drug Houses, Ltd., announce a similar reduction in the "A.B." Brand, manufactured jointly by this firm and Allen and Hanburys; and Messrs. Boots and Co., Ltd., of Nottingham, have similarly reduced their price. The new price, which came into force on July 1st, is 2*s.* 8*d.* per phial of 100 units (10 average doses).

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, JUNE 30TH.

LIQUOR (POPULAR CONTROL) BILL.

THE debate was resumed on the amendment for the rejection of the Liquor (Popular Control) Bill, moved by Lord Banbury.

Lord DAWSON said that it was common ground that the consumption of alcohol in this country was far too great, and that the nation spent far too much upon it. But in searching for a cure they needed to be watchful that their proposals did not replace one evil by another. He was not enamoured of the constant quotation of America. He did not like to think that we were so sterile in imagination that we could not find our own remedies for our own social evils. Surely the best remedy was that which was founded upon causes and emotions, and he hoped to show their lordships that this country was not only becoming temperate but in an accelerated degree; and if the conditions which were responsible for the improvement were only fostered and furthered they could face the solution of this dire problem with greater ease of mind than in the past. It might be taken that the opinion of the medical world, both in this country and abroad, was by a very large majority in favour of alcohol as a useful substance, a beneficent agent when taken in proper quantities, at proper times, and by people whom it suited. The majority of the medical profession themselves drank wine, though in strict moderation. It was perfectly true that the action of alcohol was in no way useful to those who were occupied in physical or mental labour. It was further admitted that although it was a food it was an unsuitable and wasteful food to those who were in health. But the action of alcohol on the nervous system was beneficent and useful when taken in proper quantities and at the proper time. It was almost a matter of common knowledge that a glass of alcoholic liquor at the end of the day would lighten the mental horizon, brighten the outlook, and enable a man to drop those grey-coloured spectacles with which he viewed the world after the hardships of the day, and give him content, ease of mind, and happiness. They ought to do nothing which would diminish the cheerfulness and the measure of sociability which was so helpful in helping us along our mortal road. He did not think they were helped forward by denunciations of alcohol as a narcotic. If alcohol was wrong then the whole community ought to give it up. But this Bill was class legislation, which would never interfere with the man who was able to have alcohol in his cellars.

Referring to the evidence afforded by disease regarding the effect of alcohol, Lord Dawson said that if a man had been intemperate and had an accident or was stricken by fever he was liable to develop delirium tremens. If they took the figures of one large hospital for the three decades comprised between the years 1894 and 1923 they found that, beginning at 27·8 per year, they went down to 17·6 in 1901–13 and finally to 10. Taking another well-known disease produced by alcohol—namely, cirrhosis of the liver—for the same three periods the average admissions in the first decade numbered 61·4, in the second 53·2, and in the third 20. Thirdly, there was another disease, more common perhaps among women than among men—viz., alcoholic peripheral neuritis. The figure was 23·8 in the first decade, 14·1 in the second, and 5 in the third. Side by side with those figures he would put the statistics of the consumption of beer for the same years. In the first decade the consumption was 29·52 gallons per head of the population, in the next decade 28·91, in the next 26·66, and when they came down to the last year the figure was 15·80. As to the consumption of spirits, in the first decade the figure was 0·87 gallon per head of the population, for the second decade 0·85, for the third 0·59, and at present 0·31. Quoting from 200 examples of healthy people as afforded in the experience of a big insurance company, Lord Dawson said of those over 40 years of age 21 per cent. took no alcohol, of those under 40, 40 per cent. took no alcohol, and of those who did take it only one-fourth took spirits. He would say leave these restrictive measures alone and proceed on the line that if the people were given better houses, and more recreation grounds, they would do the rest.

The debate was adjourned.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 25TH.

Tuberculous Naval Invalids.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty whether any of the tuberculous naval invalids included in the 97·9 percentage for 1923, considered to be non-attributable to service, had questioned the opinion arrived at by naval medical boards; and whether an opportunity would be afforded these men to appeal to an independent tribunal if and when the institution of an appeal tribunal was approved.—Mr. AMMON replied: The answer to the first part of the question is in the affirmative. As regards the second part of the question, the matter is still under consideration.

Naval Lunatic Ratings.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty why naval lunatic ratings, whose insanity was attributable to service, had their pensions withheld and appropriated to the cost of their maintenance: and whether he would consider a revision of the regulations, authorising payment of pensions in those cases to their wives or dependents.—Mr. AMMON replied: Under Section 335 of the Lunacy Act (53 Vict. c. 5) the cost of maintenance is a first charge against a lunatic's pension, and the King's Regulations do not permit the concurrent payment of pension and the provision of free maintenance of the pensioner. I am afraid that I cannot consider revision of these regulations in the sense suggested, but I would point out that under present conditions by reason of the higher rate of an "attributable" pension the wives or dependents of men whose disabilities are due to the service receive higher money allowances from Greenwich Hospital funds.

Increase in the Population and Housing.

Mr. ERNEST SIMON asked the Minister of Health whether he was aware of Prof. Bowley's recent estimate that the rate of increase of the population of Great Britain would steadily become less during the next two decades, and that the population would actually become stationary about 1941; and whether he had taken any steps to investigate this estimate, which had so vital a bearing on the question of how many new houses would be needed during the next 15 years.—Mr. WHEATLEY replied: Perhaps I may refer the hon. Member to the very carefully prepared statement by the Registrar-General's department on the factors governing the growth of our population and the tendencies at present discernible, which is contained in Appendix V. of the recently issued report of the Overseas Settlement Committee (Command Paper 2107). The broad conclusions at which the department arrive are that we are at present too near the war and too much involved in the abnormalities resulting from it to attempt with confidence any estimate of the future movement of population, but that there is no safe ground for assuming that there has yet been any in the University was conferred on Prof. O. W. Richardson, F.R.S., in respect of his part-time appointment as Director of Research in the Department of Physics at King's College. Prof. Richardson will cease to hold the Wheatstone Chair of Physics, which he has occupied since 1914, on taking up the Yarrow Research Professorship of the Royal Society on August 1st next.—Nine grants were made out of the Dixon Fund for the year 1924–25 for researches, among which were the following, to be carried out at the College or Institution designated :—To William E. Downey the sum of £50 for (*a*) the spectroscopic study of luminescences and flames, more particularly that of phosphorus; (*b*) the relation between chemical action and light emission. (Imp. Coll., R.C.S.) To Violet M. Grubb the sum of £20 for the continuation of investigation into the structure and reproduction of certain red and green algæ (more particularly the delimitation of species in *Cladophora* and *Gelidium*, and the investigation of spermatial stages in the *Florideæ*). (Botanical Laboratory, Westfield College.) To Alan S. Parkes the sum of £50 for research on the physiological factors governing the proportions of the sexes in mammals, with the object of finding some means whereby the proportions may be controlled. (Institute of Physiology, University College.) To Eric A. Spaul the sum of £50 to continue experiments with the anterior lobe pituitary gland, and to gain further knowledge of the properties of the active principles of this portion of the gland, and also its biochemical properties. (Zoological Laboratory, Birkbeck College.) To Florence M. Wood the sum of £50 for chemicals and apparatus in connexion with research upon the chemical nature of the cellulose membrane. (Probably Birkbeck College.) To Muriel Bond the sum of £20 for research on "The Dietetic Factors Influencing Reproduction." (Physiological Laboratory, London School of Medicine for Women.)

The following doctorates were conferred :—D.Lit.: C. Delisle Burns (London School of Economics) for a thesis entitled "Psychological Data and Moral Standards in Contemporary Industry." D.Sc. in Physiology: J. A. Hewitt (King's College) for a thesis entitled "Metabolism of Carbohydrates (Part III.)." D.Sc. in Physiology: F. M. R. Walshe (University College and University College Hospital Medical School) for a thesis entitled "(i.) The Physiological Significance of the Reflex Phenomena in Spastic Paralysis of the Lower Limbs; (ii.) On Certain Tonic or Postural Reflexes in Man, with Special Reference to the so-called 'Associated Movements'; (iii.) On Variations in the Form of Reflex Movements, notably the Babinski Plantar response, under Different Degrees of Spasticity and Under the Influence of Magnus and de Kleijn's Tonic Neck Reflex."

Prof. H. R. Kenwood was appointed representative (in respect of University College) at the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis to be held in London in July, 1924.—The Maudsley Hospital has been admitted as a School of the University in the Faculty of Medicine for the purpose of research in psychological medicine.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.—The fifth annual general meeting of the society will take place at the Adam Hall, 12, Stratford-place, London, W., on Thursday, July 10th, at 5.30 P.M., when the President, Sir Auckland Geddes, will deliver his first presidential address. Dr. J. H. Sequeira, Lady Askwith, Captain Walter Elliot, M.P., and Mr. H. Wansey Bayly will also speak.

DIPLOMAS IN PSYCHOLOGICAL MEDICINE. — The Universities of Cambridge, London, Durham, Leeds, Manchester, and Edinburgh, and the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England now grant Diplomas in Psychological Medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses. Details can be obtained from the various examination bodies. In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been recognised as a school of the University of London. The course consists of two parts, and is adapted for the Diploma of the Conjoint Board, the University of London, or the University of Cambridge, Part I. being conducted by Sir Frederick Mott, Dr. F. Golla, and Dr. Henry Devine, and Part II. by Sir Frederick Mott, Dr. Bernard Hart, Dr. Golla, Dr. F. C. Shrubsall, Dr. W. C. Sullivan, Dr. C. Hubert Bond, and Dr. E. Mapother. Appointments as clinical assistants are obtainable at the hospital, and the holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. Further particulars as to the lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5, and as to clinical facilities to the medical superintendent of the hospital.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—At the annual general meeting of the association, held on June 26th, the following were elected officers for the year 1924–25 :—President: Dr. G. de B. Turtle. Vice-Presidents: Dr. A. Parkin and Mr. C. W. Hope. Hon. Secretaries for North and South: Dr. S. W. Davidson and Dr. F. W. M. Pratt respectively. Hon. Treasurer: Dr. W. D. Forrest.

BRITISH ASSOCIATION.—The annual meeting of the British Association for the Advancement of Science to be held in Toronto in August will be under the presidency of Major-General Sir David Bruce. The President will deliver the opening address on August 6th on the Prevention of Disease, and will deal with the experience in this field gained during the war. Five hundred members of the Association will travel to Canada for the meeting, which will begin on August 7th and continue until August 13th. The sectional presidential addresses will include discourses on Chemistry and the State, by Sir Robert Robertson; Inter-Racial Problems and White Colonisation in the Tropics, by Prof. J. W. Gregory; and Academic Freedom in Universities, by Principal Ernest Barker.

ROYAL SANITARY INSTITUTE. — The Thirty-fifth Congress of the Royal Sanitary Institute will be held at Liverpool from July 14th to 19th under the presidency of Lord Salisbury. The Congress will consist of 11 sections, and will deal with many aspects of hygiene, in particular maternity and child welfare, public health education, and the value of voluntary public health work. Food and feeding in their several aspects, including milk in its production and also water-supply, will come under discussion. There is a Conference specially devoted to port sanitary authorities, in which ship sanitation will be discussed. As a practical demonstration of many of the subjects, a large health exhibition is held in connexion with the meeting. Among those who will preside over the different sections are Lieut.-General Sir William Leishman, Dr. T. M. Legge, Dr. E. W. Hope, and Dr. T. W. Naylor Barlow. A large attendance is expected, which will consist mainly of officers and representatives of Government departments, municipal and public health departments in the United Kingdom, and including also many representatives of foreign Governments, dominions, and colonies of the Empire. On July 16th Prof. H. R. Kenwood, of London University, will deliver a popular lecture on Modern Civilisation from the Health Standpoint. Full particulars of the Congress may be obtained from the secretary at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. 1.

THE LATE DR. C. BURLAND.—Dr. Charles Burland, formerly senior medical officer to the Marine Department of the Board of Trade, who died on June 29th at his residence in Southampton at the age of 63, was the eldest son of the late Rev. C. I. Burland, vicar of St. Saviour's, Shanklin. He received his early education on H.M.S. *Conway*, and at Yorkshire College, Leeds, and proceeded to the study of medicine at the University of Edinburgh and in Paris. He qualified L.R.C.P., L.R.C.S. Edin. in 1884, and in 1890 graduated with honours M.D. Brussels. During the South African war he was appointed to the medical charge of invalid troops, and obtained for his services the medal with clasp; later he served as surgeon to the P. and O. and Cunard steamship lines. In 1906 he was appointed Board of Trade medical inspector in Glasgow and for the Western District of Scotland, and in 1909 senior medical officer and Government medical inspector of emigration at the port of Liverpool. Two years later he became chairman of the Advisory Committee on Medical Equipment of Merchant Ships. He was an ex-president of the Brussels Medical Graduates' Association. Dr. Burland contributed several papers to THE LANCET dealing with points in the treatment of symptomatology of various disease conditions. He was also the author of the well-known "Ship Captain's Medical Guide," published by the Board of Trade, which has gone through 16 editions, and in 1919 he composed the official leaflet on How to Keep Clear of Influenza.

MATERNAL MORTALITY. — In a circular letter (No. 517. H.M. Stationery Office. 1*d.*) dated June 30th, addressed to local authorities, the Minister of Health calls special attention to various suggestions for the prevention and remedy of the present high rate of maternal mortality, made by Dr. Janet Campbell in her recent report on this subject, which was discussed in THE LANCET dated April 5th (p. 716) and 19th (p. 809). Of these suggestions adequate provision for antenatal supervision is regarded as of primary importance. Antenatal supervision may be given partly through the doctor or midwife engaged by the patient, but also by means of maternity centres established by the local authority.

Public Health By-laws.

Mrs. Wintringham asked the Home Secretary how many local authorities had power, under Section 85 of the Public Health Acts Amendment Act, to make by-laws with regard to the public control of agencies for domestic service, and how many had exercised such power.—Mr. Henderson replied: 96 cities or boroughs, 72 urban districts, and 2 rural districts have obtained orders declaring Section 85 in force in their areas. By-laws have been made by 38 cities or boroughs, 17 urban districts, and 1 rural district.

Eyesight Test for Omnibus Drivers.

Mr. Godfrey Locker-Lampson asked the Home Secretary whether the police were making arrangements for an eyesight test for drivers of omnibuses.—Mr. Henderson replied: For many years the production of a certificate of physical fitness has been required, and this certificate includes the question of vision.

Appeal Court for Criminal Lunatics.

Mr. Compton asked the Home Secretary whether there existed any court of appeal for the inmates of the criminal asylum at Broadmoor similar to the Court of Criminal Appeal provided for prisoners, and if not, will this question be included in the terms of reference for the Royal Commission on Lunacy.—Mr. Henderson replied: No, Sir. A verdict of guilty but insane is technically a verdict of acquittal from which no appeal to the Court of Criminal Appeal can lie. The proper authority to consider representations with respect of such a case is the Home Secretary. The answer to the second part of the question is in the negative. Questions of criminal responsibility are, I understand, outside the scope of the Royal Commission on Lunacy.

Royal Commission and Asylum Inmates.

Mr. McEntee asked the Prime Minister if he would arrange that adequate facilities be given to the inmates of asylums to bring to the notice of the Royal Commission circumstances and conditions which, owing to the secrecy prevailing in lunacy institutions, did not usually come under the cognisance of the medical officers in charge thereof.—Mr. Greenwood replied: It will rest with the Royal Commission to decide what procedure they will adopt to inquire into the points to which my hon. friend refers or receive evidence upon them. The Royal Commission will also have full power to visit mental hospitals in order to acquaint themselves with the conditions prevailing.

Royal Commission on Lunacy.

Mr. Robert Richardson asked the Prime Minister if he would give some indication as to how soon it was his intention to appoint the promised Royal Commission to inquire into the defects in the Lunacy Law and administration, and what were to be its composition and terms of reference.—Mr. Greenwood replied: A statement was published on Tuesday giving the composition of the terms of reference of the Royal Commission, and a copy will be sent to my hon. friend.

Bad Housing in Southwark.

Mr. Naylor asked the Minister of Health if his attention had been drawn to the further comments made by the Southwark coroner on the housing conditions in that borough, and to his suggestion that immediate provision should be made for the clearance of slum property and the erection of temporary accommodation for the persons so displaced, pending the building of houses under the Government scheme; and whether the Minister would consider how the problem of the slum areas could be more effectively provided for.—Mr. Greenwood replied: My right hon. friend has received a communication from the Southwark coroner on this matter. The Housing Act of 1923 provides for a Exchequer contribution on a half-and-half basis towards the cost of slum clearance schemes (including the re-housing of the occupants) undertaken by local authorities. Since 1919 11 such schemes have been confirmed in the County of London, and others are under consideration.

Housing in Rural Parishes.

Mr. Ernest Brown asked the Minister of Health the number of houses to the acre it was proposed to build in agricultural parishes under the Housing (Financial Provisions) Bill.—Mr. Greenwood replied: The matter is primarily one for the local authorities. Under the Housing Acts a cottage provided by a local authority may include a garden of not more than one acre. The general advice given by my department is that in agricultural areas houses should not, unless there are special circumstances, be built at more than eight to an acre.

Treatment of Early Mental Cases.

Mr. Robert Richardson asked the Minister of Health how many asylums had been, or are about to be, opened this year; was he aware that the Mental Hospitals' Association reported in 1922 vacancies in public asylums to the extent of 18,000 beds which had apparently been now filled up: and, in view of the increase in insanity thus indicated, an increase undoubtedly traceable to lack of preventive measures, would he reconsider the question of encouraging by Parliamentary grant the provision under health committees, as distinct from asylum committees, of hospitals quite apart from lunacy administration, where uncertifiable cases might have the benefit of such early and appropriate care as might promote their speedy recovery without the risk and detriment of being placed under lunacy control.—Mr. Greenwood replied: One new public mental hospital has been or will be opened this year. With regard to the latter part of the question I would refer the hon. Member to the reply given on June 5th.

Officers' Wound Pensions.

Sir Thomas Bramsdon asked the Minister of Pensions if, in cases of officers in receipt of pensions for wounds which were certified as not equivalent to the loss of a limb, and which the disabled officer claimed were so equivalent and produced the necessary medical evidence to that effect, he would consider whether it was possible to allow these questions affecting these officers to be dealt with by the House of Lords tribunal, as at present they had no redress further than a pension appeal board.—Mr. F. O. Roberts replied: Wound pensions are outside the scheme of final awards and the statutory Final Awards Regulations. They are in the nature of exceptional provision for a particular type of disability not determined by the general scale of assessment for disablement. Wound pensions, like wound gratuities, are administered, not under Ministry warrants, but under regulations common to the service departments and the Ministry of Pensions, and appeals are most carefully considered by a central board, which includes eminent surgeons.

St. Andrew's Mental Hospital, Northampton.

Mr. Robert Richardson asked the Minister of Health: (1) In how many cases had a petition prepared by the manager of St. Andrew's Hospital, Northampton, and presented by him to a judicial authority, for an order to detain a voluntary boarder as a lunatic been found, on examination by the Board of Control, to differ from the copy supplied to the Board by the manager under the provisions of Section 316 of the Lunacy Act, 1890; in how many such cases did the statement of a reason for not calling in the boarder's usual medical attendant appear unsigned by the petitioner in the original but signed in his name in the official copy; and in how many was the date of presentation of the petition as given by the petitioner altered in the official copy in such manner as to bring it into conformity with the date of the above-mentioned statement forming part of the petition; what steps had been taken under the direction of the Board of Control to ascertain whether any such false entries were knowingly made or whether they were due to mere accident or oversight; and what disciplinary measures had been taken in either case under the terms of Sections 318 or 320 of the Lunacy Act, 1890. (2) In how many cases in which a petition for a judicial order changing the status of a voluntary boarder at St. Andrew's Hospital, Northampton, to that of a certified lunatic, had been posted by the petitioner to the manager of this private asylum prior to its presentation to a judicial authority, and had been presented by the manager or his agent without having again been in the hands of the petitioner, had such petition been found, on examination by the Board of Control, to contain an entry in the handwriting of the manager or his agent bearing a date subsequent to the date appearing in the handwriting of the petitioner against his signature; and in how many such cases had it been made to appear in the copy sent to the Board of Control that the petitioner signed on the later date, by the substitution in the copy of the later date for the earlier date given by the petitioner against his signature.—Mr. Wheatley replied: There has been one such case. As the hon. Member is aware, the details of this case have already received full consideration, not only by the Board of Control, but by the courts; and no disciplinary measures have been deemed necessary.

Monday, June 30th.

Government and the Summer Time Bill.

Sir Kingsley Wood asked the Prime Minister whether the Government would now provide facilities for the Summer Time Bill.—The reply was: The Government have decided to adopt this Bill, which they desire to see passed into law this session.

Cost of Public Health Services.

Lieut.-Colonel Horlick asked the Chancellor of the Exchequer what was the total cost of our public health services, including that of National Health Insurance and the grants in aid for services administered by the Ministry of Health and the Board of Education; what proportion was paid by the State and what by the local authorities: and whether he could give an estimate of the cost of the proposed revision of the Public Health Acts that was under permanent departure from the conditions which during the last 50 years have resulted in a natural increase of approximately 400,000 per annum for Great Britain.

Poor-law Officers and Poor-law Reform.

Mr. LORIMER asked the Minister of Health if, when he set up a departmental committee to consider a report upon the Poor-law administration throughout the country, he would give the Poor-law Officers' Union an opportunity to present their views.—Mr. WHEATLEY replied : There is no present intention of setting up such a departmental committee as is suggested. I have already intimated that I shall be glad to consider any suggestions which the Union may think fit to place before me.

Disinfection of East India Wool.

Mr. WARDLAW-MILNE asked the Minister of Health the intention of the Government regarding the suggested compulsory disinfection of East India wool ; whether he was aware that if this regulation was brought into force it was probable that the article secured would be inferior in quality, thus resulting in a serious handicap upon the carpet trade of this country ; whether, as it was advisable to put all buyers on equal terms if disinfection was proved to be necessary at all, he would consider the possibility of arranging for this disinfection to be carried out at the source of supply ; and if he would suspend the bringing of such an order into force pending full and proper inquiry into the whole matter.—Mr. HENDERSON (Home Secretary) replied : The whole matter is being fully considered and no decision has yet been taken. I am not aware of any foundation for the allegation in the second part of the question.

Public Enlightenment on Venereal Disease.

Mr. SNELL asked the Minister of Health whether the question of the assignment of the sum allocated for public enlightenment regarding venereal disease had yet been settled ; whether the Society for the Prevention of Venereal Disease, whose valuable work in the education of the public regarding the medical prevention of venereal disease was universally acknowledged, would receive a share of such a grant ; and whether the Ministry of Health had accepted the recommendations contained in the recent report of the committee of inquiry upon the best medical measures for preventing venereal disease in the civil community.—Mr. WHEATLEY replied : The answer to the first part of the question is No. As regards the second and third parts, I can only say that the recommendations contained in the report mentioned in the question are still under consideration.

Smoke Abatement Bill.

Mr. ERNEST SIMON asked the Minister of Health when he proposed to introduce a Smoke Abatement Bill.—Mr. WHEATLEY replied : The Bill will be introduced in another place within the next few days.

Slum Areas in London.

Mr. GILBERT asked the Minister of Health the number of slum areas in the County of London his department had given sanction to for clearance under the Housing Act of last year, and approximately the number of houses, the total area, and the number of persons such clearance schemes had dealt with.—Mr. WHEATLEY replied : Three schemes in the County of London were confirmed in 1923 and 1924, comprising 668 houses, an area of approximately 13 acres, and a population of 3760. Several other schemes are under consideration.

Women in the Ministry of Health.

Mrs. WINTRINGHAM asked the Minister of Health whether, seeing that questions as to the administration of the health insurance benefits of insured women were dealt with in the insurance branch of the Ministry of Health, how many posts there were in this branch above the lower clerical grade ; and how many of these posts were filled by women.—Mr. WHEATLEY replied : There are 385 posts in the insurance branch of the Ministry above the lower clerical grade, and of these 94 are held by women. Included in the total of 385 are 222 posts on the outdoor staff of the branch, and of these 59 are held by women.

Hospitals and Public Funds.

Mr. ALFRED T. DAVIES asked the Minister of Health how many London and provincial hospitals were supported, or receive assistance from, public funds, and what are the respective amounts allocated ; whether he was aware that over 200 beds were now closed in two hospitals in London alone for want of funds ; that over 10,000 persons in London alone had been accepted by the hospitals for operations or treatment and could not be admitted ; whether the Ministry had the hospital system of London and the provinces under review ; and what it was proposed to do, if anything, to relieve or improve the present state of affairs.—Mr. WHEATLEY replied : The Voluntary Hospitals Commission completed the distribution of the grant from public funds administered by them at the end of the last financial year. No hospitals are now receiving direct assistance from public funds, but many receive from local authorities contributions towards the cost of certain grant-aided services which are subsidised jointly from public and local funds. I am aware that two of the large London hospitals have closed beds, but more than half of the closed beds have at no time been available to the civil population, and have never been occupied except by military patients during the war. I have no exact information as to the extent of the waiting lists, but this is one of the questions now being investigated by the Voluntary Hospitals Commission, who have been asked to report on the extent of the additional accommodation required in voluntary hospitals and the best means of providing and maintaining it.

Assaults on Girls.

Sir THOMAS BRAMSDON asked the Home Secretary if he would explain what was the present position of the departmental committee which he had decided to set up to inquire into the question of assaults on girls ; and whether he was in a position to state who the members of that departmental committee would be.—Mr. HENDERSON replied : I regret the delay in setting up this committee, which has been largely due to a difficulty in connexion with the appointment of a chairman. I now hope to be in a position to proceed with the appointment very shortly.

Mercantile Officers and Eyesight Tests.

Mr. BALFOUR asked the President of the Board of Trade whether his attention had been drawn to the fact that executive officers of the mercantile marine might pass Board of Trade standards even if blind in one eye ; and, in view of the fact that such a state of things was not consistent with safe navigation and that Germany and other competing nations had a superior physical standard in this matter, whether he would have inquiry made into the matter.—Mr. ALEXANDER replied : Very careful consideration was given, some years ago, to the question whether the Board of Trade sight tests should lay down a standard for each eye, or should allow the standard of form vision required to be reached by a candidate using both eyes together, or either eye separately, at the option of the candidate. The present rule gives this option to the candidate, and accordingly it is possible, as suggested in the question, that a candidate may pass the Board of Trade sight tests even if blind in one eye. I am not aware that any serious consequences have resulted from the present rule, which has been in force since 1912, but if the hon. Member will communicate to me any evidence suggesting that the present rule has had serious consequences, I am prepared to reconsider the general question.

THURSDAY, JUNE 26TH.

Restrictions at Edenhall Hospital.

Mr. CLARKE asked the Minister of Pensions if he was aware that considerable hardship and irritation was being caused by the officer in charge at Edenhall Hospital, Musselburgh, in imposing unnecessary and unreasonable restrictions on the men under his charge and in using questionable methods in applying the regulations dealing with ordinary breaches of discipline ; and, if not, would he cause inquiry to be made with a view to securing greater harmony than at present prevails.—Mr. F. O. ROBERTS replied : At a recent inspection of this institution by medical officers, including a neurologist, two cases of complaint were brought forward, but in neither instance was the complaint established. I am not aware of any justification for the general charge made against this officer, whose conduct of the institution, which I have personally inspected within the past few days, appears to be highly efficient. I should add that neurasthenic patients, to whose treatment the hospital in question is devoted, at all times offer special difficulties in management, and the recent medical inspection showed that cases of varying types which could not suitably be associated with others had been admitted to the institution. This has now been put right by the transfer of certain cases to more suitable institutions under the Ministry.

Pensioners and Final Appeals.

Mr. JOHN GUEST asked the Minister of Pensions whether, in view of the failure of many appellants to the final appeals court to understand the medical précis supplied them by the Ministry in preparation for such appeal and also their inability owing to illness or the effect of wounds adequately to present their case, the pension authorities would make some suitable provision by which the appellant in presenting his claim might have the assistance of his local doctor, who was in most instances familiar with the case.—Mr. F. O. ROBERTS replied : Under the rules made by the Lord Chancellor, the tribunal is required to assist any appellant who, through ignorance or otherwise, is unable to make the best of his case. Moreover, the tribunal is empowered at its discretion to summon before it expert or other witnesses to give oral evidence. Any question as to an extension of this provision would be a matter for the consideration of the Lord Chancellor.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 7th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Dr. Burrell: Medical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M. Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THURSDAY, July 10th.—5 P.M., Mr. Richard Lake: Intra-Cranial Complications of Middle-Ear Diseases. (Geoffrey E. Duveen Lectures in Otology.)

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-street, W.C.

THURSDAY, July 10th.—4 P.M., Mr. Barrington Ward: Intestinal Obstruction.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

TUESDAY, July 8th.—5 P.M., Dr. Haldin Davis: Acne.

Appointments.

CASTLE, W. F. L., M.B., Ch.B., has been appointed Assistant House Surgeon, Jessop Hospital for Women, Sheffield.

COBB, G. F., M.R.C.S., L.R.C.P. Lond., Senior Assistant Medical Officer and Deputy Medical Superintendent of the Burntwood County Mental Hospital, near Lichfield, Staffs.

CUBBON, H. T., M.B., B.Ch. Camb., Second Electro-Therapeutist, Royal Sussex County Hospital.

HOBLING, J. H., L.M.S.S.A. Lond., Certifying Surgeon under the Factory and Workshop Acts for Lostwithiel.

LANE-ROBERTS, C. S., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon to Out-patients, Queen Charlotte's Maternity Hospital.

ROLSTON, J. R., L.R.C.P. Edin., M.R.C.S., Consulting Ophthalmic Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

YOUNG, A., M.B., C.M. Glasg., one of the Medical Referees under the Workmen's Compensation Act for the County of Lanark.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal Mineral Water Hospital.—S.
Birmingham, Queen's Hospital.—Surg. Reg. £100.
Blackburn, Calderstones, Whalley.—Asst. M.O. £440 16*s.* 11*d.*
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—R.M.O.
Coventry and Warwickshire Hospital.—H.P. £150. Also Jun. H.S. £130.
Durham, Richard Murray Hospital, Blackhill.—R.M.O. £400.
Gilbert and Ellice Islands Colony.—Sen. M.O. £650.
Guy's Hospital.—Part-time M.O. in Venereal Dis. Dept. £550.
Guy's Hospital Dental School, London Bridge, S.E.—Sen. Dent. O. and Clin. Tutor. £300.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Gynæcologist.
Hong-Kong University, Faculty of Medicine.—Professor of Obstetrics and Gynæcology. £800.
Hospital for Consumption and Diseases of Chest, Brompton.—R.M.O. and Reg. £500. Also H.P. £50.
Hull City Mental Hospital.—Sen. Asst. M.O., &c. £600.
King's Lynn, West Norfolk Hospital.—Res. Surg. O. £300–£350.
Leeds Public Dispensary.—Sen. Res. M.O. £200.
Leicester Royal Infirmary.—H.P. £125.
Liverpool Royal Infirmary.—Hon. Asst. P.
London Hospital.—Second Reg. to Ear, Nose, and Throat Dept.
Margate, Royal Sea Bathing Hospital.—H.S. £200.
Metropolitan Hospital, Kingsland-road, E.—Asst. Dent. S.
Middlesex Hospital, W.—Res. M.O. £250.
Northampton County Mental Hospital, Berrywood, near Northampton.—Locum Tenen's M.O. £8 8*s.* weekly.
Northampton General Hospital.—Sec. Supt. £400.
Norwich, Norfolk and Norwich Hospital.—Anæsth. £300.
Queen's Hospital for Children, Hackney, E.—Asst. Cas. H.S. £100. Also Asst. S. to Ear, Nose, and Throat Dept.
Royal Army Medical Corps.—20 Commissions.
Royal Chest Hospital, City-road, E.C.—P. to Out-patients.
Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and H.S.
Royal National Orthopædic Hospital, 234, Gt. Portland-street, W.—Reg. and Clin. Asst. 100 guineas.
St. Bartholomew's Hospital.—Asst. Administrator of Anæsthetics.
St. Bartholomew's Hospital Medical College.—Demonstrator of Physiology.
St. Mary's Hospital, W.—Cas. H.S. £100.
St. Mary's Infirmary, Highgate-hill.—A.M.O. £350.
St. Thomas's Hospital.—Visiting Anæsth.
Sheffield Children's Hospital.—H.S. £125.
University College Hospital, Gower-street, W.C.—Tub. O. £300.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Ophth. S.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
West London Hospital, Hammersmith-road, W.—Asst. Anæsth.
Wolverhampton and Staffordshire Hospital.—Pathologist and Bacteriologist. £600.
York City Mental Hospital, Fulford.—Asst. M.O. £440.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Castleton, Yorks, North Riding; and Melling, Lancs.

Births, Marriages, and Deaths.

BIRTHS.

BOWES.—On June 27th, at de Vaux-place, Salisbury, the wife of G. K. Bowes, M.D., M.R.C.P., of a son.

DUNLOP.—On June 19th, at Elm Cottage, Hendon, to Dr. Doris Howard, wife of Dr. W. A. L. Dunlop—a daughter.

GIRDWOOD.—On April 18th, at Johannesburg, the wife of Dr. R. L. Girdwood, of a daughter.

GRANT.—On June 27th, at York, the wife of Major M. F. Grant, R.A.M.C., of a daughter.

MARRIAGES.

WILSON—LAMPORT.—On June 24th, at the Parish Church, Lancaster, by the Rev. J. W. N. Bardsley, vicar, assisted by the Rev. J. L. Gamble, vicar of Milnthorpe, Henry Wilson, *M.C.*, M.B., Ch.B., of "Whitmore," Gatley, Cheshire, son of Henry Wilson, M.R.C.S., and Mrs. Wilson, of Cheadle, Cheshire, to Florence Marjorie Lamport, M.B., Ch.B., younger daughter of H. C. Lamport, M.B., C.M., and Mrs. Lamport of Lancaster.

DEATHS.

DOW.—On June 22nd, at Comely Park House, Dunfermline, William Barrie Dow, M.D., F.R.C.S. Edin., LL.D., in his 89th year.

FERGUSON.—Robert Bruce Ferguson, M.A., M.D. Cantab., D.P.H., &c., at "Marton" Catherine-road, Surbiton, formerly of New Southgate.

PENNY.—On June 22nd, at Liverpool, Dr. Alfred Ferguson Penny, F.R.C.S. Irel., late of Chelsea, in his 59th year.

STEWART.—On June 30th, at Melville-street, Edinburgh, Charles Hunter Stewart, M.B., C.M., D.Sc., Professor of Public Health, University of Edinburgh, aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

A CONVENIENT OPERATION TABLE.

WE have received from Messrs. Mayer and Phelps a descriptive catalogue of recent surgical instruments and appliances of interest to physicians and surgeons. Of these, the "Empire" general operation table now being shown at the Scientific Instrument section of the Palace of Industry at the British Empire Exhibition has been designed with a view to getting the utmost strength and rigidity of construction, combined with simplicity in obtaining the various positions required. The base and tilting gear are each formed of one casting; the frame of the top is of seamless steel tubing, all joints being welded. The top is of phosphor-bronze, and other portions of the table liable to wear are made or covered with the same material. The construction ensures absolute rigidity and stability at any height and in any position, the various parts being carefully machined and the screw gears well-fitted. There are no cog-wheel gears in any part to cause shake. The table stands on four bronze feet, which are capable of adjustment for the purpose of levelling; they are shaped so as to render it an easy matter to slide the table along the floor. The height of the table can be altered while the patient is in any position by means of an oil pump actuated by the foot. The range is from 3 ft. 5 in. in its highest to 2 ft. 9 in. in its lowest, the latter allowing of the correct Trendelenburg position. A kidney bridge is an integral part of the table, being actuated by means of a simple lever giving a direct lift without any complicated gear.

A movable lamp for the operating table is fitted with ball-bearing castors. The lamp consists of an upright and an arm six feet long terminating in a group of four lamps with parabolic reflectors giving a shadowless light of approximately 800 candle power; the base is made sufficiently heavy to give good stability.

OPHTHALMIC BENEFIT COMMITTEE.—A meeting of this committee will take place on July 7th, at 5.30 P.M., in the Council Chamber of the British Medical Association.

consideration.—Mr. W. GRAHAM (Financial Secretary to the Treasury) replied: The statements below give the figures asked for in the first two parts of the question. As regards the last part of the question, the revision of the Public Health Acts, which is now under consideration, is intended primarily as a preliminary to consolidation and there is no reason at present to think that any amendments will result in a material addition to the cost of local administration.

STATEMENT A.—The latest available figures as to the expenditure (other than out of loans) by local authorities in England and Wales on public health services (excluding services carried on by local education authorities) relate to the year 1921–22 and are summarised in the following table:—

Services.	Expenditure (other than out of loans).	Sources from which expenditure was met—		
		Specific receipts in aid of the service—		
		Fees, tolls, rents, and other receipts not being grants or rates.	Government grants.*	Rates and other unallocated receipts.
	£	£	£	£
Sewers and sewage disposal	8,918,025	754,299	219,933	7,973,793
Collection and disposal of house refuse ..	7,874,393	457,890	11,185	7,405,318
Scavenging and watering of roads and streets	(Approx.) 4,450,000	Not ascertained.	—	(Approx.) 4,450,000
Hospitals, sanatoria, dispensaries, &c., for Tuberculosis .	3,338,150	472,820	1,936,564	928,766
Venereal dis..	452,639	10,377	407,277	44,985
Fever, diphtheria, smallpox, &c. ..	4,320,877	207,597	4,249	4,109,031
Salaries of M.O.H.'s, inspectors of nuisances, health visitors†	1,345,259	9,796	389,174	946,289
Maternity and child welfare..	2,003,722	472,423	882,556	648,743
Baths, wash-houses, and open bathing places	1,803,912	774,969	11,197	1,017,746
Parks and open spaces	3,920,652	898,064	298,812	2,723,776
Vaccination ..	178,558	—	10,323	163,235
Port sanitary service	104,639	17,701	45,464	41,474
Cemeteries ..	1,463,462	901,989	24,088	537,385
Water-supply .	16,437,690	12,613,969	32,053	3,791,668
Other health services	1,856,497‡	478,861	6,370	1,371,266
—	58,503,000	18,070,000	4,278,000	36,152,000

---

* The figures entered under Government grants are in some cases based in expenditure incurred before 1921–22 and *include grants made in respect of schemes of work for the unemployed.* Expenditure in respect of lunatics and lunatic asylums, mental deficiency, Poor-law infirmaries, and other Poor-law institutions for the sick, and housing and town planning is not included above.

† So far as not allocated to specific services.

‡ Includes approximately £15,000 in respect of expenditure on the welfare of the blind.

Public Health Expenditure (Voluntary Agencies).

	Expenditure.	Exchequer share.
Maternity and child welfare ..	£400,000	£230,000
Welfare of the blind	£450,000	£700,000

STATEMENT B.—*National Health Insurance* (calendar year 1922):—

Expenditure	£26,000,000
Exchequer share	7,500,000

STATEMENT C.—*Board of Education School Medical Service* (1922–23):—

Expenditure	£1,234,000
Exchequer share (approximately)	600,000

Surgeon-Commanders' Pensions.

Dr. SPERO asked the Parliamentary Secretary to the Admiralty whether the increased pensions granted to senior surgeon-commanders, Royal Navy, were regarded as a measure of compensation for their compulsory premature retirement; and if they were liable to a reduction with the fall in the cost of living.—Mr. AMMON replied: The earlier ages of compulsory retirement were introduced as a part of the new scheme of pay and allowances, &c., in 1919. This scheme must be considered as a whole and no particular item of it can be regarded as a set-off against another particular item. The answer to the last part of the question is in the affirmative.

TUESDAY, JULY 1ST.

Age Disqualification and Sickness Insurance.

Mr. WILLIAM HENDERSON asked the Minister of Health whether his attention had been drawn to the fact that workmen over 70 years of age who were in employment paid their national health insurance contributions, though they were not eligible for sickness benefit; and whether, seeing that these men were afraid of losing their employment if they disclosed their age, he would include in the terms of reference to the committee of inquiry into the national health insurance the desirability of permitting persons to draw sick benefit irrespective of age, so long as they continued to pay the insurance contributions.—Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is aware of the point raised by my hon. friend. The terms of reference of the Royal Commission would enable the question of the extension of the title to sickness benefit to persons over 70 years of age to be considered.

Remuneration of Army Medical and Veterinary Officers.

Mr. JAMES GARDNER asked the Secretary of State for War whether, seeing that officers of the Army Medical and Veterinary Services who were originally remunerated on a civilian basis were now placed on the army officers' basis, he would take the necessary action to place the emoluments of the officers of the staff for Royal Engineer Services on a military basis; and whether, seeing that the civilian officers of the army chaplain's department, who had always been on the civilian basis, were in 1920 placed on the army officers' basis for retired pay, he would extend the same privilege to the officers of the staff for Royal Engineer Services.—Major ATTLEE (Financial Secretary to the War Office) replied: As regards future entrants, the question of placing their pay and retired pay on a military basis is under consideration. But there is no intention, for the reasons I have already explained, of altering the present basis for the existing permanent officers of the staff for Royal Engineer Services.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, Thursday, and Friday, July 9th, 10th, and 11th.

SUB-SECTION OF PROCTOLOGY (Section of Surgery): Annual Clinical Meeting in conjunction with the American Proctologic Society:—

Wednesday.

11 A.M. Reception by the President (Mr. Aslett Baldwin).
Papers:
Dr. Jackson (President, A.P.S.): "Quo vadis?"
Dr. Beach: The Evolution of Proctology.

5.30 P.M.
Discussion:
The Injection Treatment of Hæmorrhoids, to be opened by Mr. Graeme Anderson.

Thursday.

4.30 P.M.
Discussions:
The Treatment of Pruritus Ani, to be opened by Dr. Montague (New York). The Treatment of Rectal Prolapse, to be opened by Dr. Hirschman (Detroit).

Friday.

4.30 P.M.
Discussion:
The Treatment of Cancer of the Rectum, to be opened by Mr. W. Ernest Miles and Mr. Lockhart-Mummery.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, July 7th, to SATURDAY, July 12th.—ROYAL EYE HOSPITAL, Southwark. Clinical Cases daily at 3 P.M. except Saturdays. Mon., 5 P.M., Mr. T. W. Letchworth: Optic Neuritis. Tues., 5 P.M., Mr. W. J. Lindsay: Squint. Wed., 5 P.M., Mr. A. D. Griffith: Conjunctivitis. Thurs., 5 P.M., Mr. T. W. Letchworth: The Treatment of Epiphora and Mucocele. Fri., 5 P.M., Mr. E. A. Dorrell: Glaucoma.—ST. PETER'S HOSPITAL FOR STONE. Clinical Work and Special Lectures Daily (last week).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, July 7th.—11 a.m., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. Bishop Harman: Eye Dept.

Tuesday.—10 a.m., Dr. Drummond Robinson: Gynæcological Operations. 11 a.m., Mr. Endean: Venereal Diseases. 2 p.m., Dr. Burrell: Medical Out-patients.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 12.15 p.m., Dr. Burnford: Medical Pathology. 2 p.m., Dr. Owen: Medical Out-patients.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Dept. 2 p.m., Mr. Simmonds: Surgical Out-patients. 2 p.m., Mr. Bishop Harman: Eye Dept.

Friday.—10 a.m., Mr. Dudley Buxton: Dental Dept. 2 p.m. Mr. Sinclair: Surgical Out-patients. 2 p.m., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

Thursday, July 10th.—5 p.m., Mr. Richard Lake: Intra-Cranial Complications of Middle-Ear Diseases. (Geoffrey E. Duveen Lectures in Otology.)

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-street, W.C.

Thursday, July 10th.—4 p.m., Mr. Barrington Ward: Intestinal Obstruction.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

Tuesday, July 8th.—5 p.m., Dr. Haldin Davis: Acne.

Appointments.

Castle, W. F. L., M.B., Ch.B., has been appointed Assistant House Surgeon, Jessop Hospital for Women, Sheffield.

Cobb, G. F., M.R.C.S., L.R.C.P. Lond., Senior Assistant Medical Officer and Deputy Medical Superintendent of the Burntwood County Mental Hospital, near Lichfield, Staffs.

Cubbon, H. T., M.B., B.Ch. Camb., Second Electro-Therapeutist, Royal Sussex County Hospital.

Hobling, J. H., L.M.S.S.A. Lond., Certifying Surgeon under the Factory and Workshop Acts for Lostwithiel.

Lane-Roberts, C. S., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon to Out-patients, Queen Charlotte's Maternity Hospital.

Rolston, J. R., L.R.C.P. Edin., M.R.C.S., Consulting Ophthalmic Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

Young, A., M.B., C.M. Glasg., one of the Medical Referees under the Workmen's Compensation Act for the County of Lanark.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal Mineral Water Hospital.—S.

Birmingham, Queen's Hospital.—Surg. Reg. £100.

Blackburn, Calderstones, Whalley.—Asst. M.O. £440 16s. 11d.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—R.M.O.

Coventry and Warwickshire Hospital.—H.P. £150. Also Jun. H.S. £130.

Durham, Richard Murray Hospital, Blackhill.—R.M.O. £400.

Gilbert and Ellice Islands Colony.—Sen. M.O. £650.

Guy's Hospital.—Part-time M.O. in Venereal Dis. Dept. £550.

Guy's Hospital Dental School, London Bridge, S.E.—Sen. Dent. O. and Clin. Tutor. £300.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Gynæcologist.

Hong-Kong University, Faculty of Medicine.—Professor of Obstetrics and Gynæcology. £800.

Hospital for Consumption and Diseases of Chest, Brompton.—R.M.O. and Reg. £500. Also H.P. £50.

Hull City Mental Hospital.—Sen. Asst. M.O., &c. £600.

King's Lynn, West Norfolk Hospital.—Res. Surg. O. £300–£350.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Leicester Royal Infirmary.—H.P. £125.

Liverpool Royal Infirmary.—Hon. Asst. P.

London Hospital.—Second Reg. to Ear, Nose, and Throat Dept.

Margate, Royal Sea Bathing Hospital.—H.S. £200.

Metropolitan Hospital, Kingsland-road, E.—Asst. Dent. S.

Middlesex Hospital, W.—Res. M.O. £250.

Northampton County Mental Hospital, Berrywood, near Northampton.—Locum Tenen's M.O. £8 8s. weekly.

Northampton General Hospital.—Sec. Supt. £400.

Norwich, Norfolk and Norwich Hospital.—Anæsth. £300.

Queen's Hospital for Children, Hackney, E.—Asst. Cas. H.S. £100. Also Asst. S. to Ear, Nose, and Throat Dept.

Royal Army Medical Corps.—20 Commissions.

Royal Chest Hospital, City-road, E.C.—P. to Out-patients.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and H.S.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W.—Reg. and Clin. Asst. 100 guineas.

St. Bartholomew's Hospital.—Asst. Administrator of Anæsthetics.

St. Bartholomew's Hospital Medical College.—Demonstrator of Physiology.

St. Mary's Hospital, W.—Cas. H.S. £100.

St. Mary's Infirmary, Highgate-hill.—A.M.O. £350.

St. Thomas's Hospital.—Visiting Anæsth.

Sheffield Children's Hospital.—H.S. £125.

University College Hospital, Gower-street, W.C.—Tub. O. £300.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Ophth. S.

Warrington Infirmary and Dispensary.—Jun. H.S. £175.

West London Hospital, Hammersmith-road, W.—Asst. Anæsth.

Wolverhampton and Staffordshire Hospital.—Pathologist and Bacteriologist. £600.

York City Mental Hospital, Fulford.—Asst. M.O. £440.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Castleton, Yorks, North Riding; and Melling, Lancs.

Births, Marriages, and Deaths.

BIRTHS.

Bowes.—On June 27th, at de Vaux-place, Salisbury, the wife of G. K. Bowes, M.D., M.R.C.P., of a son.

Dunlop.—On June 19th, at Elm Cottage, Hendon, to Dr. Doris Howard, wife of Dr. W. A. L. Dunlop—a daughter.

Girdwood.—On April 18th, at Johannesburg, the wife of Dr. R. L. Girdwood, of a daughter.

Grant.—On June 27th, at York, the wife of Major M. F. Grant, R.A.M.C., of a daughter.

MARRIAGES.

Wilson—Lamport.—On June 24th, at the Parish Church, Lancaster, by the Rev. J. W. N. Bardsley, vicar, assisted by the Rev. J. L. Gamble, vicar of Milnthorpe, Henry Wilson, *M.C.*, M.B., Ch.B., of "Whitmore," Gatley, Cheshire, son of Henry Wilson, M.R.C.S., and Mrs. Wilson, of Cheadle, Cheshire, to Florence Marjorie Lamport, M.B., Ch.B., younger daughter of H. C. Lamport, M.B., C.M., and Mrs. Lamport of Lancaster.

DEATHS.

Dow.—On June 22nd, at Comely Park House, Dunfermline, William Barrie Dow, M.D., F.R.C.S. Edin., LL.D., in his 89th year.

Ferguson.—Robert Bruce Ferguson, M.A., M.D. Cantab., D.P.H., &c., at "Marton" Catherine-road, Surbiton, formerly of New Southgate.

Penny.—On June 22nd, at Liverpool, Dr. Alfred Ferguson Penny, F.R.C.S. Irel., late of Chelsea, in his 59th year.

Stewart.—On June 30th, at Melville-street, Edinburgh, Charles Hunter Stewart, M.B., C.M., D.Sc., Professor of Public Health, University of Edinburgh, aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

A CONVENIENT OPERATION TABLE.

We have received from Messrs. Mayer and Phelps a descriptive catalogue of recent surgical instruments and appliances of interest to physicians and surgeons. Of these, the "Empire" general operation table now being shown at the Scientific Instrument section of the Palace of Industry at the British Empire Exhibition has been designed with a view to getting the utmost strength and rigidity of construction, combined with simplicity in obtaining the various positions required. The base and tilting gear are each formed of one casting; the frame of the top is of seamless steel tubing, all joints being welded. The top is of phosphor-bronze, and other portions of the table liable to wear are made or covered with the same material. The construction ensures absolute rigidity and stability at any height and in any position, the various parts being carefully machined and the screw gears well-fitted. There are no cog-wheel gears in any part to cause shake. The table stands on four bronze feet, which are capable of adjustment for the purpose of levelling; they are shaped so as to render it an easy matter to slide the table along the floor. The height of the table can be altered while the patient is in any position by means of an oil pump actuated by the foot. The range is from 3 ft. 5 in. in its highest to 2 ft. 9 in. in its lowest, the latter allowing of the correct Trendelenburg position. A kidney bridge is an integral part of the table, being actuated by means of a simple lever giving a direct lift without any complicated gear.

A movable lamp for the operating table is fitted with ball-bearing castors. The lamp consists of an upright and an arm six feet long terminating in a group of four lamps with parabolic reflectors giving a shadowless light of approximately 800 candle power; the base is made sufficiently heavy to give good stability.

Ophthalmic Benefit Committee.—A meeting of this committee will take place on July 7th, at 5.30 p.m., in the Council Chamber of the British Medical Association.

Notes, Comments, and Abstracts.

CHRONIC LEAD POISONING AMONG POTTERY WORKERS.[1]

BY FRANK SHUFFLEBOTHAM, M.D. CAMB.,
M.R.C.P. LOND.,
MEDICAL ADVISER TO THE NATIONAL SOCIETY OF POTTERY OPERATIVES OF GREAT BRITAIN AND IRELAND.

FOR many years past public attention has been attracted to the number of cases of lead poisoning in the pottery industry of this country, and for more than 20 years I have been closely interested in the medical welfare of the men and women who live in the district in which I was born.

The Potteries of North Staffordshire.

Unfortunately, I cannot submit a favourable report with regard to workers engaged in lead processes. Roughly speaking, there are between 60,000 and 70,000 men, women, and girls employed in the pottery industry in this country, and North Staffordshire can be claimed to be the most important pottery centre in the whole world. There are nearly 5000 employees engaged in processes which expose them to lead poisoning. The pottery industry is not confined to England only; it is, next to agriculture, the oldest handicraft, and has been practised in every country alike in ancient and in modern times, and yet the Staffordshire potter has been able to hold his own for hundreds of years in the markets of the world. What applies to Staffordshire applies also to other pottery districts. There are many counties in England, Scotland, Ireland, and Wales where pottery is produced, and where lead processes are involved, but I wish to confine my remarks principally to lead poisoning as found among lead workers in North Staffordshire. It is estimated that in the North Staffordshire district at the present time there are 2600 working in lead processes, 1300 in lead processes of what is called a low solubility glaze, and 800 in what is assumed to be leadless glaze, and the nature of the employment is as follows: Leadhouse men, 100; dippers and ware cleaners, 1650; glost placers, 1900; glost oddmen, 450; majolica paintresses, 150; groundlayers, 150; aerographers, 300.

The leadless glaze factories are mainly those factories which make electric fittings, stilts and spurs, Longton china, and sanitary fire-clay ware. About 10 per cent. of pottery workers are engaged in lead processes, and although the Home Office figures show a reduction in the incidence of lead-poisoning cases, they do not disclose the real facts. I admit that the various investigations that have been made with regard to this industry have prompted the Home Office to make such regulations as have practically wiped out acute cases of lead poisoning; but when a man has worked in lead for 20 years, even under conditions such as the Home Office has laid down, there is not the slightest doubt his employment has exercised a great detrimental influence on his health and shortened his life by many years. The medical men in North Staffordshire have learnt a great deal through the wise action of Mr. Hugh Worthington Adams, the county coroner for the district, in insisting upon post-mortem examinations being made upon all lead workers, and the information so acquired has shown conclusively that life has been shortened and death accelerated as a result of the men's employment in lead processes. Further, by these examinations a great deal of light has been thrown upon the action of lead and lead salts upon the human system.

The Diagnosis of Lead Poisoning.

Lead poisoning cannot be diagnosed at sight like broken arms and broken legs. In view of the fact that there are now practically no cases of acute lead poisoning, those of chronic lead poisoning require very careful investigation. The symptoms of chronic lead poisoning during life are those of general arterio-sclerosis. There is hypertrophy of the heart, a high blood pressure, and the urine invariably shows a low specific gravity. With regard to albuminuria and casts, these are not invariably present, but with the low specific gravity and frequent micturition, especially during the night, a fairly safe conclusion as to the condition of the kidneys can be formed. Among the lead poisoning cases which have been under my care at the North Staffordshire Infirmary, it has been my practice to have the urine for each day collected and samples examined, and even when there has been no doubt that the patient was suffering from lead poisoning, some days elapse before albumin is found in the urine. The high blood pressure may rise to extraordinary heights. I had recently a patient who had been in bed for two weeks, and whose blood pressure rose to 260 mm. Hg and, strange to say, he recovered. A few days ago I examined a lead worker who had travelled four miles to see me and who was undoubtedly suffering from lead poisoning with a blood pressure equal to 200 mm. Hg. Anæmia is a well-known concomitant of lead poisoning, and the examination of the blood shows a diminished percentage of hæmoglobin and frequent basophilic granulation of the red blood corpuscles.

The subjective symptoms of this complaint are headaches, constipation, vomiting, abdominal colic, pains in the arms and legs, shortness of breath, and giddiness. In some cases there is wrist-drop, but I do not think this symptom is as frequent as it was 20 years ago. In view of the fact that acute cases are now practically non-existent, eye trouble does not occur except as a complication of general arterio-sclerosis. Although many manufacturers now use low solubility glazes, and are thereby reducing the risk of lead poisoning among their operatives, yet low solubility glaze is by no means free from danger, and may itself cause lead poisoning in a marked degree. One reason for this may be that the dust arising from a low solubility glaze is composed of much finer particles than that from the ordinary glaze. One case in particular which has come under my notice recently is that of a young woman who had never worked in an ordinary lead glaze, but who worked for about four or five years in a low solubility glaze. She is undoubtedly suffering from lead poisoning, and is, in fact, now receiving full compensation in respect of it.

Lead poisoning is not an untreatable disease. The experience of the physicians at the North Staffordshire Infirmary shows that even a comparatively short treatment with rest in bed, good diet, and a course of suitable medicine effects a marked improvement in the patient's condition.

Medico-legal Aspects of Lead Poisoning.

The medico-legal aspect of lead poisoning is of extreme importance, because in many cases victims of the industry are deprived of their just rights through the unjust laws of this country as embodied in the Factory Act and the Workmen's Compensation Act. The monthly examination by the certifying factory surgeon has undoubtedly had a great beneficial influence on lead workers, both in the pottery industry and in other industries where lead processes are employed; but, on the other hand, the mere fact that the certifying factory surgeon can suspend a lead worker from his employment (in which he may have been engaged for 30 or 40 years) on the ground that he is unsuited to work in lead processes because he is presumed to be suffering from lead poisoning, is a manifest injustice. Under these circumstances the worker can claim no compensation under the Workmen's Compensation Act. The Workmen's Compensation Act does not act fairly towards lead workers. It has been so worded that county court judges, who sympathise with the workers in these dangerous industries, have been rendered helpless. In any dispute between the worker and the employer as to whether the former is suffering from lead poisoning or not, the case must be submitted to a medical referee appointed by the Home Office before the workman can obtain compensation. I contend that a single examination is not sufficient in cases of suspected chronic lead poisoning to decide the matter in dispute. It very often takes me a week to make a decision in doubtful cases, and in most instances I have found it to be to the benefit of the patient that I have delayed my decision.

Post-mortem Aspects of Lead Poisoning Cases.

I have attended all the post-mortem examinations on lead workers in North Staffordshire for some years past, and the principal features in these examinations have been: (1) hypertrophy of the heart with atheroma of the aorta and the aortic valves; (2) granular and contracted kidneys, with very little cortex; (3) in some instances, cerebral hæmorrhage; (4) rarely, constriction of the large intestine; (5) occasionally, blue line round the anus. (In the last ten years I have only seen a blue line round the gums in three cases.)

In conclusion, I wish to say that I am only anxious that what I regard as the most beautiful industry in this country should be worked under conditions such that the men and women employed in it might lead the healthiest lives.

---

[1] A paper read at the First International Congress of the People's League of Health at Wembley on May 23rd, 1924.

A WELL-ORGANISED EXPEDITION.

A FIRST-AID compartment in charge of trained nurses was a feature of each of the eight special trains which conveyed the employees of Boots Pure Drug Co., Ltd., from Nottingham to Wembley on June 21st. Further precautions taken to ensure the comfort of the party included rooms booked in a London hotel for those who might miss trains, and a special fleet of trams and buses to convey to their homes those employees living in country districts. The arrangements were carried out for the directors, who bore all the expenses, by the Boots Welfare Department under Major T. Knowles.

Observations
ON THE
DIAGNOSIS OF DIPHTHERIA:
COMBINED BACTERIOLOGICAL AND CLINICAL EVIDENCE.

BY F. FOORD CAIGER, M.D., F.R.C.P. LOND.,
CHIEF MEDICAL OFFICER, INFECTIONS HOSPITAL SERVICE, M.A.B.;
AND
R. A. O'BRIEN, C.B.E., M.D. MELB., D.P.H.,
DIRECTOR OF THE WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES.

THE investigation described in this paper was made in order to see if laboratory methods, applied as thoroughly as possible to every case admitted with a diagnosis of diphtheria into an infectious fever hospital, would be helpful. In other words, would the extra time and trouble involved in such work give any real help (*a*) in the interests of the patient, (*b*) in the interests of hospital administration?

Procedure.

The patients were admitted to the South-Western Hospital of the Metropolitan Asylums Board. From every patient admitted with a diagnosis of diphtheria a swab was taken in the receiving-room by the medical officer on duty, and a clinical diagnosis made by her and entered in the record as "diphtheria," "probably diphtheria," "not diphtheria," or "probably not diphtheria." The first two groups are considered as a positive admission-room diagnosis of diphtheria, and appear in Table I. as $b+$; the two latter are recorded as a negative admission-room diagnosis, and appear as $b-$. The swab was sent to the Wellcome Physiological Research Laboratories some six miles away, where it was usually received the same day, and sown on Löffler's medium. From the swab a "direct smear" was made, and stained by Gram's method, in order to detect Vincent's organisms or streptococci, if present. After incubation for 18 to 24 hours a smear was made from the culture, and if organisms morphologically indistinguishable from K.L.B. were found, the laboratory diagnosis was entered as "M.D.B." Throughout this paper "M.D.B." is used to indicate bacilli morphologically indistinguishable from the *Bacillus diphtheriæ*; this is essentially a microscopic diagnosis. "K.L.B." is used to indicate a bacillus which microscopically appears to be *B. diphtheriæ*, isolated in pure culture, which ferments glucose but not saccharose, and may be virulent or avirulent to guinea-pigs.

The culture made from the swab on Löffler's medium and allowed to grow overnight was in most cases injected intradermically into guinea-pigs. From the swab or the culture on Löffler's medium plates were always sown, and one or more colonies picked off, grown for 24 hours, and injected intradermically into guinea-pigs.[1] In special cases the subcutaneous method was also used. If the provisional diagnosis made did not agree with the clinical diagnosis, a second swab was asked for. Thus the clinical and laboratory workers each had, while the patient was available, the opportunity of reviewing the diagnosis in view of the other's evidence.

The clinical work fell mainly on Dr. Amy Thoms and Dr. Ruby Inkster; the laboratory work was carried out by Dr. A. J. Eagleton (in the earlier part of the series), and Dr. C. C. Okell, Dr. H. J. Parish, and Miss M. Baxter throughout. From time to time the results were reviewed in conference by the above workers together with ourselves. Since the whole problem was approached from the clinical standpoint, the final decision in all cases rested with the clinician.

Results.

The investigation was carried on until 700 swabs had been examined. They are divided into two series, G, 1 to 600, and A, 1 to 100; 520 patients in all were examined. In Table I. are given the general results. If we consider for the moment series G, 1 to 600, it will be noted that in the case of 58·3 per cent.—i.e., cols. B, F, G, and D—of all patients certified before admission as "bacteriological" or "clinical" diphtheria, the diagnosis was confirmed, while in 41·7 per cent.—i.e., cols. C and E—the original diagnosis could not be confirmed either clinically or bacteriologically. It is not suggested that this whole group represents definite errors in clinical diagnosis made by outside practitioners. Some of these "negative" patients had probably had clinical diphtheria a few days previously, and were "clearing up" when admitted. We must also remember that the general practitioner or the medical officer in a general hospital is often faced with a situation in which he considers it justifiable to send the patient to a fever hospital as a precautionary measure or on grounds of expediency.

a, Laboratory diagnosis. *b*, Admission-room diagnosis. *c*, Final clinical diagnosis.

Col. D: From nine cases virulent bacilli were isolated when the "admission diagnosis" and the final clinical diagnosis were negative. These would seem to be patients who had yielded a "positive" result during the swabbing of contacts or routine swabbing of schools or families. All nine carriers within a few weeks gave a succession of negative swabs. It is worthy of remark that col. D—i.e., the "carriers"—represents only 2 per cent. of the total admissions. We anticipated that most of the cases considered clinically negative by the hospital staff would have fallen into this group, whereas they fall into the group in which both the bacteriological and clinical evidence failed to confirm the diagnosis made before admission.

Col. E: Here the laboratory worker failed to find bacilli in one or more swabs and the clinician made the final diagnosis negative, though on admission the condition of the patient had justified a provisional clinical diagnosis of "probably diphtheria."

Col. G: These 11 cases are of considerable interest; in Table II. are given details.

TABLE II.—*Clinical Diagnosis Positive, but Laboratory Diagnosis Negative in all 11 Cases.*

Four or more negative swabs..	2
Very few M.D.B.; not isolated	2
Avirulent (several colonies examined) ..	2

The notes from these cases have subsequently been carefully considered in conference; the laboratory workers' evidence in all these instances—i.e., the examination by cultural and inoculation tests—have failed to yield the results which are regularly obtained in frank clinical diphtheria. The clinicians, on the other hand, on reviewing the clinical records, felt that the course of the illness so closely resembled frank clinical diphtheria that a diagnosis of diphtheria was the only one open to them.

---

[1] Eagleton and Baxter: Brit. Med. Jour., 1921, i., 775.

The only point of outstanding interest is that in several of these instances the patient was admitted late in the course of a severe attack and received serum at a late stage of the disease; one would have expected some paralytic or myocardial symptoms to appear during convalescence, but this expectation was not realised and in none did these symptoms appear. More than one of these patients was shown to a class of students and a prognosis of paralysis during convalescence made, but no paralysis developed. Clinically, these cases certainly did not resemble syphilitic pharyngitis. It may be that the illness in these patients was caused by Vincent's organisms or streptococci. We are of the opinion that few, if any, of these cases can be thus explained, for we were naturally alive to these possibilities and had examined direct smears in every case.

From two patients avirulent organisms only were isolated. When the result of the virulence test was known some days had elapsed, and the opportunity of getting a second swab at an early stage of the disease had disappeared. The facts relating to these two patients are recorded above; virulent organisms may have also been present in the throat, but the swab either failed to collect any virulent organisms or collected extremely few, which could not be isolated. The few investigations that have been made indicate that probably more than 1 per cent. of the general population in London carry avirulent K.L.B. in their throats. Among 554 patients sent into a hospital one would expect to find a small number carrying avirulent K.L.B., in addition to the causal virulent organisms. The laboratory workers have found, in a total of approximately 2000 examinations in the past few years, three instances of the association of virulent and avirulent K.L.B. in the same culture, one from a healthy carrier, one from a convalescent patient, and one from a case of diphtheria.

The examinations in series A, 1 to 100, were carried out before those in series G, and before the arrangements for rapid interchange of results were working as smoothly as during the later G series. The general results resemble those of series G, except that under cols. G and H 20 per cent. of the patients appear, whereas in series G col. H is unnecessary, and col. G contains only 2·5 per cent. Without emphasising the point too far, we are inclined to believe that, as the general result of this earlier work, the clinician came to feel that the laboratory evidence gave definite aid, and that where the "admission diagnosis" and the laboratory diagnosis did not agree there was a gradually increasing tendency to revise the "admission diagnosis." The results obtained from series A are not represented in the percentages quoted throughout the paper and in the general discussion.

The following points of interest emerged during the inquiry:—

1. In 95·5 per cent. of cases in which the diagnosis of diphtheria was confirmed, the first swab sent to the laboratory was found to be positive, and it is worthy of note that by the technique adopted virulent *B. diphtheriæ* were isolated from 93·5 per cent. (Table III.).

TABLE III.—*Clinical Diagnosis Positive in 245 Cases.*

	Cases.		Percentage.	
First swab positive—				
K.L.B. isolated—Virulent ..	229	234	93·5	95·5
,, ,, —Avirulent ..	2		0·8	
Very few M.D.B. present, not isolated	3		1·2	
Swab negative		11		4·5

2. In five cases in a total of 436—i.e., 1·15 per cent. —later examination changed a negative laboratory diagnosis, which had been based on the examination of the first swab, into a positive diagnosis.

3. Amongst 234 patients where the clinical diagnosis was positive and M.D.B. were seen in the smear, isolation of virulent organisms was successful from the first swab in 231 instances, while in three instances —i.e., 1·2 per cent.—M.D.B. were seen in the first swab but could not be isolated, whereas from a second swab virulent K.L.B. were obtained.

4. Three laryngeal cases occurred in the series; from one virulent K.L.B. were obtained; from two, with a clinical diagnosis "uncertain, ? laryngeal diphtheria," no M.D.B. were obtained in culture.

5. In only two instances the clinical diagnosis was "nasal diphtheria," but from neither were K.L.B. obtained.

6. Amongst 182 cases clinically negative, no M.D.B. were obtained from cultures in 167 instances—i.e., 91·7 per cent.; in 11 instances—i.e., 6 per cent.—very few M.D.B. were seen in the smear made from an overnight culture, but could not be isolated. It is probable that none of these were true K.L.B.

From four only avirulent K.L.B. were isolated. From the cultures obtained from each of these four patients a number of colonies were examined for virulence.

Summary of Results.

1. Approximately 529 patients certified as suffering from diphtheria and admitted to the South-Western Hospital were included in the examination; 436 of them were closely studied. In 59 per cent. the diagnosis of diphtheria was confirmed. In 41 per cent. the diagnosis could not be confirmed.

2. Only nine cases, or approximately 2 per cent. of the whole, were healthy "carriers" of virulent *B. diphtheriæ.*

3. The laboratory workers' diagnosis agreed with the clinical diagnosis in 97·5 per cent. of instances; in 11 cases (2·5 per cent.) the laboratory evidence was directly against a diagnosis of diphtheria, while the clinical evidence was quite definitely in favour. No completely satisfactory explanation of these discrepancies suggests itself.

4. The first swab examination at the laboratory was found to be positive in 95·5 per cent. of instances in which the diagnosis of diphtheria was confirmed. From 93·5 per cent. virulent diphtheria organisms were isolated. In only 1·15 per cent. was a negative diagnosis which had been made from the first swab changed into a positive diagnosis by the examination of later swabs.

5. Two cases only were diagnosed as "nasal diphtheria," but from neither were *B. diphtheriæ* isolated.

Conclusions.

With regard to the questions set forth at the beginning of the inquiry we can answer:—

1. There is no evidence that the information obtained by the inquiry has altered or improved the prognosis or treatment of the patients suffering from diphtheria.

2. From the administrative point of view the inquiry has been justified; we feel that the investigation has resulted in an increased confidence and accuracy of diagnosis amongst the clinicians taking part. It should therefore facilitate the allocation of patients to the different wards in the hospital and ensure their release in "negative" cases at an earlier date than would be justifiable without full coöperation with the laboratory worker.

3. The accuracy of hospital statistics is much improved by the coöperation of the laboratory worker.

4. From the point of view of accuracy of diagnosis, we are definitely of opinion that laboratory facilities similar to those described should be available in all large hospitals for infectious fevers.

The amount of laboratory work was very large, and it is probable that after this preliminary careful exploration of the field information of similar value can continuously be supplied by the laboratory worker, even if he dispenses with the routine animal tests and trusts to isolation and fermentation tests of pure colonies. The true *B. diphtheriæ* invariably and rapidly ferments glucose, but never saccharose. The animal test should be available in doubtful or difficult cases.

The only point of outstanding interest is that in several of these instances the patient was admitted late in the course of a severe attack and received serum at a late stage of the disease; one would have expected some paralytic or myocardial symptoms to appear during convalescence, but this expectation was not realised and in none did these symptoms appear. More than one of these patients was shown to a class of students and a prognosis of paralysis during convalescence made, but no paralysis developed. Clinically, these cases certainly did not resemble syphilitic pharyngitis. It may be that the illness in these patients was caused by Vincent's organisms or streptococci. We are of the opinion that few, if any, of these cases can be thus explained, for we were naturally alive to these possibilities and had examined direct smears in every case.

The amount of laboratory work was very large, and it is probable that after this preliminary careful exploration of the field information of similar value can continuously be supplied by the laboratory worker, even if he dispenses with the routine animal tests and trusts to isolation and fermentation tests of pure colonies. The true *B. diphtheriæ* invariably and rapidly ferments glucose, but never saccharose. The animal test should be available in doubtful or difficult cases.

a rate depending on the rapidity of the healing process. At length, after several weeks, the end of the diaphysis shows a normal structure and the previous rickets is only to be detected by the contrast shown between its fine close structure and the coarse-grained appearance of the structure of the bone-shaft.

The *calcium content of the bone* also increases with the beginning of the healing process. This is best shown in the development of the so-called "osteophyte layer" of periosteal fibrous tissue which forms a more or less close sheath around the shaft of the bone. The rate of healing was compared with that of similar cases receiving untreated cod-liver oil (see Wimberger, 1923). In cases of therapy with untreated crude cod-liver oil, the first signs of healing were apparent after about 2–3 weeks (14–24 days); in the present case the period varied from two to five weeks, and especially in regard to the later course of the recovery, the rate of healing in these observations was definitely slower than with untreated cod-liver oil. The course of healing was not observed to differ in any way from that observed in X ray with other therapeutic agents (sunlight or mercury-quartz lamp radiation).

Case Histories.

CASE 1.—F. G., male, aged 6 months. Admitted Feb. 7th, 1923. Child cannot sit alone, skeleton shows swellings at the epiphyses, well-marked rosary, no craniotabes, dimensions of fontanelle 4 by 4·5 cm. Clinical examination otherwise negative, with the exception of rhinitis with a slight pharyngeal murmur. Tuberculin reaction negative. X ray examination showed active rickets in moderate degree. Feb. 8th: Therapy begun with oxidised cod-liver oil, gradually increasing dose from 4 to 20 g. daily of a 50 per cent. emulsion. 12th to 28th: Respiratory infection with middle-ear inflammation and pneumonia. March 1st: Unchanged in X ray. 8th: Normal temperature, increasing in weight, obstinate rhinitis. and bronchitis. X ray shows suggestion of healing at the proximal end of the fibula. 15th: X ray picture shows distinct signs of healing in tibia and fibula. 22nd: Marked improvement in general condition. X ray photograph shows healing of the skeleton to be progressing. 29th to May 10th: X ray shows progressive healing of bone lesions at a slow rate. May 12th: Lungs free, chronic rhinitis. Can sit with support. June 7th: Skeleton shows well-calcified regular ends to the bone-shafts, with wide, thick osteophyte layer; healing almost complete.

CASE 2.—H. M., male, aged 9 months. Admitted Feb. 13th, 1923. Moderately well nourished. Skeleton shows strongly-marked rosary, slight craniotabes with some hydrocephalus, dimensions of the great fontanelle 3 by 3 cm., no teeth, moderate swellings at the joints. X ray shows active rickets of moderate grade, slender bones with well-marked calcium deficiency; the ends of the metaphyses with finely fringed outlines; suggestion of osteophyte layer at radius and ulna. Feb. 14th to April 15th: Preliminary period of observation without special therapy. Child had chicken-pox, but made good recovery and gain in weight. X ray examinations during this period showed bone lesions to have remained unchanged. April 15th: Therapy begun with oxidised cod-liver oil; dose gradually raised to 20 g. daily 50 per cent. emulsion. First attempts to crawl. 24th: X ray picture unchanged. May 1st: First definite signs of healing shown in X ray by deposition of calcium in the distal metaphysis of the ulna. 15th: Good progress in healing of the bone lesions shown in X ray. Acute attack of bronchitis with fever and loss of weight. 24th: Extraordinarily quick progress in the repair of bone lesions. Recovering from bronchitis; gaining in weight. June 19th: Healing of rickets far advanced. 23rd: Discharged.

CASE 3.—E. B., male, aged 5 months. Admitted March 23rd, 1923. Nutrition good, skin clear, œdema present in both feet. Skeleton shows well-marked rosary and severe craniotabes; dimensions of fontanelle 3 by 3·5 cm., no teeth. Chvostek test definite, tendon reflexes increased. Spleen not palpable. Tuberculin test negative. Slight bronchitis. X ray shows active rickets with moderate degree of calcium deficiency; the ends of the shafts are slightly cupped and markedly fringed in outline. March 24th: Frequent attacks of laryngospasmus. April 1st: Therapy began with oxidised cod-liver oil, gradually increasing from 2 to 20 g. daily of a 50 per cent. emulsion. 7th: X ray examination shows no change. The Chvostek sign disappears promptly after doses of 10 per cent. ammonium chloride. Slight increase in body-weight. 14th: Doubtful signs of healing in X ray at proximal ends of tibia and fibula. 21st: Definite healing visible in X ray in femur, tibia, and fibula. 25th: Middle-ear inflammation following a cold infection. 28th: General condition good, putting on weight, can sit with support. X ray shows *deposition* of calcium to be far advanced in the healing metaphyses at the proximal ends of the tibia and fibula, and to a less degree at the distal ends of the ulna, radius, and femur. May 26th: X ray shows healing process to be almost complete. 29th: Discharged.

CASE 4.—A. F., male, aged 12 months. Admitted April 27th, 1923. Child in poor general condition, had recovered from measles one week before admission; very pale and thin. Skeleton shows marked rosary and swollen joints, soft skull with hydrocephalus; *dimensions of the* fontanelle 3 by 3·25 cm.; two teeth. Child has a potbelly, spleen hard and palpable two fingers' breadth below the rib margin; enlarged liver. Bad croupy cough with dyspnœa, action of alæ nasi obvious in breathing, fine râles over the apex of the right lung. Tuberculin test negative. X ray examination shows severe active rickets, with marked calcium deficiency, very coarse structure of spongy bone, the ends of the metaphyses frayed, green-stick fracture of the right fibula. April 27th to June 27th: X ray shows condition of the skeleton to remain unchanged. During this period the child suffered from a severe attack of bronchial pneumonia, making a fair recovery. Severe anæmia with marked splenic enlargement. June 28th: Administration of oxidised cod-liver oil begun. July 4th: Cough and cold infection, fever, severe anæmia (Hb=35, Sahli). 25th: Recovered. X ray photograph shows suggestions of healing at the ends of all metaphyses. August 2nd: Healing definitely apparent in X ray at the distal end of ulna and radius, and at the proximal end of tibia and fibula. The anæmia and general condition better. 15th: Healing shows slow progress. Anæmia slowly improving, spleen unchanged; 1 per cent. solution of tartar emetic given intravenously. Sept. 5th: X ray shows a fresh distinct line of calcification at the epiphyseal end of the wide rachitic zone. Oct. 10th: The ends of the bone-shafts regular in contour. Good general condition, can stand with support. Therapy with *untreated* cod-liver oil begun. Oct. 27th: Discharged. General *condition* good, rachitic bone lesions almost healed.

Conclusions and Summary.

1. Four cases of active rickets in infants, aged from 5 to 12 months, were treated with oxidised cod-liver oil (heated for 24 hours at 120° C. with air bubbled through). The daily dose was 10 g. and the cases, carefully controlled with regular X ray examination, showed satisfactory healing of the bone lesions at a rate rather slower than with the same dose of a potent, crude, untreated cod-liver oil.

2. The growth-promoting potency of the two samples of oil, tested by growth experiments on rats, was found to be in the ratio of about 1 : 20.

3. Assuming that a daily dose of 10 g. untreated cod-liver oil, when used in therapy of rickets, does not provide any great excess of anti-rachitic principle, these observations lend support to the view that cod-liver oil contains two active organic factors: (1) *anti-rachitic* or calcium-depositing, and (2) growth-promoting (vitamin A), and that the latter is the more sensitive to oxidation at a high temperature.

Our thanks are due to Dr. Zilva for kindly supplying the sample of oxidised cod-liver oil, to the Lister Institute for a supply of the purified materials used in the basal diets for the animal experiments, and to the Medical Research Council for a grant in aid and for other help. We want to express special thanks to Miss Harriette Chick, who kindly helped us, not only in the translation, but also by her constant advice and interest in the matter.

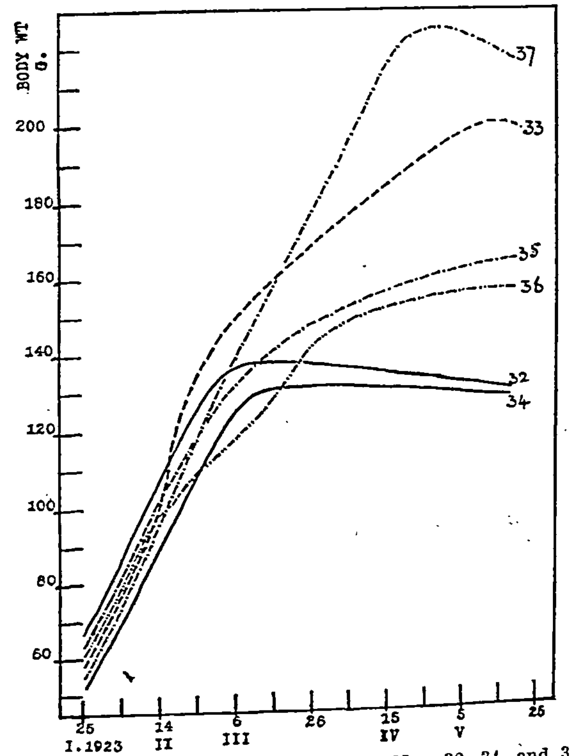
(*Continued at foot of next page.*)

cure, a fact which usually can only be determined after two or three consecutive weekly X ray examinations. The children's diet was for the most part that usual for infants in the clinic; full cows' milk with sugar, and cereal foods prepared with sugar and full milk, lemon-juice or orange-juice being added as anti-scorbutic.

The oxidised cod-liver oil "V.1." was kindly provided for us by Dr. Zilva, of the Lister Institute, London. The oxidation had been carried out at a temperature of 120° C. for 24 hours in a current of oxygen. The oil was tested by means of growth experiments with rats for its content of vitamin A and compared with a potent sample of untreated cod-liver oil. The basal diet employed and the general methods used for these experiments were the same as those used by Hume (1923) in this clinic. Young rats of about 50 g. body-weight were placed upon a diet complete in every respect but deficient in vitamin A. After weight had become stationary, the oil to be tested was added, the daily dose being fed to each rat with a pipette. The weight curves of these animals are given in the accompanying Figs. 1 and 2.

Fig. 1 shows the effect of untreated ("P.C.") and oxidised oil ("V.1."). The three animals receiving the oxidised oil "V.1." had 10 drops daily. At the end of the four months' observation the three animals receiving this oil showed the general symptoms of vitamin-A deficiency: retarded growth, enophthalmus, conjunctivitis, numerous small hæmorrhages on the eyelids, staring coat, discoloured teeth, lethargy, and loss of appetite. In no cases was there actually keratomalacia. A daily ration of 10 drops of the oxidised cod-liver oil was, therefore, not adequate to maintain normal growth and to prevent the effects of vitamin-A deficiency.

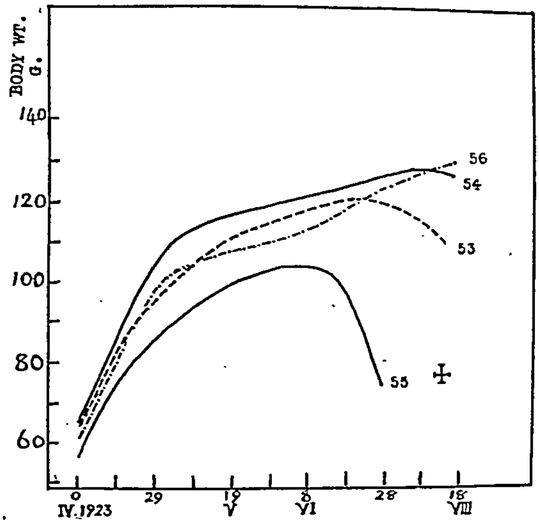
FIG. 1.



Weight curves of rats on "–A" diet. Nos. 32, 34, and 36 received in addition 10 drops daily oxidised cod-liver oil "V.1." Nos. 33, 35, and 37 received 1 drop untreated cod-liver oil "P.C." every second day until March 8th–12th, afterwards 1 drop every day.

The three animals receiving the untreated oil "P.C." had a comparatively small dose: 1 drop every other day for the first six to seven weeks and afterwards 1 drop daily. Nevertheless, their final body-weights were greater than those of the "V.1." animals, and two of the three (Nos. 33 and 37) approached the maximum weight of normal rats at their period of growth. There was no symptom of vitamin deficiency nor any trace of conjunctivitis; and there was a definite accession of growth when the daily dose was increased to a whole drop daily. We calculate, therefore, that the limiting values of the two samples of oil with regard to growth-promotion and prevention of xerophthalmia were, oxidised to untreated, as 1 to 20.

FIG. 2.



Weight curves of rats on "–A" diet. Nos. 53 and 54 received in addition daily 10 drops oxidised cod-liver oil "V.1."

Fig. 2 shows growth curves of two animals, 53 and 54, who received 10 drops oxidised cod-liver oil, "V.1.," daily, in comparison with two other animals, 55 and 56, who received the basal "–A" diet without any addition. The curves show that the oxidised cod-liver oil in the doses used by us may be regarded as free from vitamin A.

The clinical observations were made upon four cases, three moderately severe and one severe, all in the active stage. The X ray signs were unmistakable: very coarse structure of the spongy bone in the shafts, a more or less irregular frayed contour at the ends of the shafts, especially at the more quickly-growing metaphyses, at the distal ends of femur, radius, and ulna; in addition, a general diminution of calcium content markedly demonstrated in the faint shadows given by the centres of ossification.

The *effect of the therapy* was determined by means of X ray photographs which, as was shown by the researches of Chick and co-workers in this clinic (1922, 1923) and by many American observers, not only enables a trustworthy judgment to be made as to the stage of the bone lesions, but also clearly demonstrates all the fine details of the healing process.

The picture of active rickets given above showed no alteration in a preliminary period of about eight weeks' observation without special therapy, in Cases 2 and 4. Only when healing began, after treatment, was a fine cross-way band of shadow visible, several millimetres removed from the frayed end of the shaft, corresponding to the formation of a new preparatory zone of calcification at the end of the uncalcified rachitic tissue which had developed during the period of the active rickets. This new deposition of calcium marks the beginning of normal endochondral ossification and of normal growth in length in the cartilaginous zone. Deposition of calcium then takes place in the area between the new zone of provisional calcification and the end of the shaft, at weaker action, comprises the two Merck cholesterins; and Group III. only a Kahlbaum cholesterin (V.), which was of very low value. Since these investigations thus have shown that different samples of cholesterin may vary considerably, it would perhaps be desirable that each consignment of extract should be accompanied by some of the identical cholesterin which has been used in the estimation of the suspension factor, making it also possible to test the value of the cholesterin to be used. It would, naturally, be best if, by an alteration of the composition of the extract, the reaction could be strengthened, so that the cholesterin could be dispensed with, as proposed by Renaux.[3] This would be of advantage in another way, for, as will be seen from Table II., the strengthening of the reaction which is obtained by the addition of cholesterin is very different for the various sera: if, for instance, Serum No. 2 is strengthened 98 per cent., Serum No. 7 only 38 per cent. of Group I.'s cholesterins, the same sera are strengthened 51 per cent. and 7 per cent. of Group III.'s cholesterins. The addition of cholesterin thus causes a change in the original relative strengths of the various sera.

2. *Closing of Tubes for Rendering Sera Inactive* (S. and S.-G.R.).—Dreyer and Ward direct that the inactivation of the sera should be carried out by isolation in tubes plugged with cotton-wool, since they find that a tightly closed tube (closed with cork or rubber or sealed in flame) often causes a weakening of the reaction, as the process of inactivation takes place under a certain pressure.

If Meinicke's "trübungs" reaction is carried out on the same sera, wadding plugs may often prove unsatisfactory as *even small* pieces of cotton flock in the serum may cause unspecific reactions. In our Institute we therefore used rubber corks until Prof. Dreyer recently drew attention to the fact that this involved the danger mentioned above. The investigation into the importance of this was made in the following way: each serum was divided into two tubes of the same diameter containing an equal quantity, after which one was closed with a plug *of wadding and the* other with a rubber cork. After inactivating in the usual manner the S. and S.-G.R. were carried out on the various serum samples. With the S.R., the result was that this was in some cases weakened by inactivating in tubes with tight rubber corks. As a sum total, 35 sera were examined, and of these the weakening was in: 13 cases 0; 10 cases, 0–10 per cent.; 8 cases, 10–25 per cent.; 4 cases, 25–50 per cent. Sera for the S.R. should therefore be inactivated in tubes closed with a loose plug of cotton-wool and not with cork or rubber.

With the S.-G.R., 20 sera were examined. These were titrated quantitatively (with falling doses of serum). In no case was it possible to determine any weakening of the reaction by inactivating in tubes closed with rubber corks in contrast to tubes closed with a cotton-wool cork. This is probably due to the shorter period of inactivation.

3. *Fluctuations in the Temperature of Inactivation* (S. and S.-G.R.).—In their first report Dreyer and Ward directed that inactivation should be continued for 90 minutes at 53°–54° C. The temperature was raised later[4] to 55°; S.-G.R. inactivates in 30 minutes at 55° C. Six sera were tested, of which a sample was inactivated 90 minutes at 53°, 54°, 55°, 56°, 57° C. respectively. The result of the test is summarised in Table III.

TABLE III.

Σ u = Σ units.

The table shows that the strength of the S.R. declines with increasing the inactivating temperature, commencing at 54° C., and that the weakening is not proportionate to the temperature, the rate of weakening increasing considerably for every degree the temperature rises. As far as the S.-G.R. is concerned, no perceptible weakening of the reaction was determined until the temperature got beyond 56°; this is presumably due to the rather imperfect quantitative method, which does not permit of the determination of slighter weakening than 25–50 per cent., and also to the fact that the weakening is less with the shorter period of inactivating. It must therefore be strongly advised, especially as regards the S.R., that great care be taken that the temperature of the inactivating water bath is kept absolutely constant.

4. *Nature of the Water Bath* (*Sigma*).—In their work Dreyer and Ward emphasise the importance of carrying out the S.R. in a water bath and not in a dry air incubator, as the latter is said to give much weaker reactions. On the other hand, they do not indicate whether the water bath ought to be closed or open. As in our institute we generally use large, well-insulated water baths with fairly tight lids and containing 60 to 80 litres of water (the temperature thus being kept more constant and dust being kept out), used, for instance, for the W.R., these have until recently been also used for the S.R. During the International Serological Conference mentioned previously, we learned, however, that most investigators (Dreyer and Ward included) had used small open water baths. The experiments mentioned at the commencement of this work (the sending of the same serum samples to various laboratories) and later on the work of the Copenhagen Conference, showed that the values obtained for the S.R. compared with the W.R. were obviously weaker than those found elsewhere. It therefore appeared to me necessary to try whether this could possibly, to any degree, be due to the use of the covered water baths. A number of sera were pipetted in duplicate, one set being placed in a little open water bath, the other in the covered water bath generally used, both of them in such a way that half the liquid in the tubes

SOME FACTORS INFLUENCING THE FLOCCULATION METHODS OF DREYER-WARD AND SACHS-GEORGI.

By I. R. MÖRCH.

(*From the State Serum Institute, Denmark. Director: Dr. Th. Madsen.*)

SINCE Dreyer and Ward in 1921 published their quantitative sero-reaction—Sigma reaction (S.R.)[1]—for the diagnosing of syphilis, this has, after a series of experiments made on the initiative of the Hygienic Committee of the League of Nations,[2,3] and the Medical Research Council,[4] been acknowledged in most quarters as an excellent diagnostic reaction, just as sensitive—and perhaps more so—than the various modifications of Wassermann's reaction (W.R.), and of high specificity. Some of the experimenters (Houston, Boyd Campbell, Smyth, Rankin and Hall, Stokes and Wigham,[4] Mörch and Thaysen,[5] Mörch, Boas, Pontoppidan[6]) devoted themselves also to the quantitative side of the reaction, and have accordingly found that the method is sufficiently exact* to enable one to follow the result of treatment. It therefore seemed possible that in the S.R. one might possess a standard reaction which, provided that the reaction was carried out exactly according to the directions, would give fully comparable results in any laboratory whatever; but, as the following shows, this involved greater difficulty than had been expected.

In connexion with the researches instituted by the Hygienic Committee of the League of Nations, a number of syphilitic sera were divided into small portions, placed, sterile, into ampoules and sent out to various laboratories (Drs. Harrison and Wyler, London; Prof. Hirszfeldt, Warsaw; Dr. Renaux, Brussels) where they were examined the same day. The results obtained proved to be far from comparable, as will be seen from the following examples taken from the report on the subject to the Hygienic Committee of the League of Nations[3]:—

No.	Σ Units per c.cm.			
	London.	Warsaw.	*Copenhagen.*	*Brussels.*
21	6·8	5·2	1·8	13·4
29	6·8	5·9	3·0	27
40	8·3	5·6	1·8	27
42	8·3	10·1	3·0	34
52	29·5	53	5·5	>54
58	27·0	237	50	>54

In November–December, 1923, an International Serological Conference was held in Copenhagen at the instance of the Committee of Hygiene of the League of Nations, for the purpose of making comparative examinations into the various methods in use for the sero-diagnosis of syphilis. A number of modifications of W.R. were tested, as well as Meinicke's reaction[3] (modification "D.M."), Sachs-Georgi's reaction (S.-G.R.), the S.R. and Meinicke's "trübungs" reaction. The principal results of the work of the conference were, that all the flocculation reactions were perceptibly inferior as regards sensitivity to several of the Wassermann methods used. As regards the S.R., this created considerable surprise, as most of the members of the conference had already had opportunity to determine the absolute superiority of the S.R. over the Wassermann method used by them.

Investigation into the Importance of Details.

The experiments first mentioned of sending samples of the same serum to various laboratories had shown that—contrary to expectation—quantitatively corresponding results with the † S.R. were not obtained, and later on the work of the international conference showed that this rather unaccountable lack of stability might have considerable influence upon the sensitivity of the reaction. It therefore occurred to me that it might be useful to examine to what degree the S.R. is dependent upon various small details which had hitherto not been closely examined, such as slight fluctuations in the temperature of the water baths used, the use of various kinds of cholesterin, the carrying out of the reaction in an open or a closed water bath, the factor so strongly emphasised by Dreyer and Ward that those parts of the Sigma tubes which contain the liquid must be one-half to two-thirds covered by the water in the water bath. As the weakness of flocculation reactions observed during the International Conference included all these contingencies, the relation of the S.-G.R. to these factors was also included in the examination.

This examination comprised the following points: (1) Use of various kinds of cholesterin; (2) the importance of inactivating serum in tubes closed by rubber corks instead of in tubes plugged with cotton-wool; (3) the importance of slight fluctuations in the temperature at which the serum is rendered inactive; (4) the placing of the tubes in an open or in a closed water bath; (5) the importance of fluctuations in the temperature at which the reaction is begun; (6) the importance of the Sigma tubes being immersed in the water in the manner directed.

In all the examinations the directions given by the respective writers were adhered to exactly in all details. The tests were made in especially carefully calibrated tubes. The calculations of the strength of the Sigma reactions were in all cases made on the average of two readings with flocculations from St+ to tr. as a base. The S.-G.R. was also titrated quantitatively, as there is a 50 per cent. fall in the serum quantity in each successive tube, the strength of the reaction being expressed by the reciprocal value of the lowest serum dose, which gave a certain finely granulated precipitate. As the measured serum doses were pipetted decreasing with 50 per cent. for each tube (largest dose 0·2 c.cm. in total volume 0·75 c.cm.) the accuracy of this value is, however, only approximate.

1. *The Use of Various Kinds of Cholesterin* (*S.R.*).—Eight different samples were tested, one of my own making, five of Kahlbaum's, and two of Merck's. The tests were made so that to the same Sigma extract was added the prescribed quantity of cholesterin and a number of sera titrated quantitatively with the extract-cholesterin suspensions thereby produced as antigen. All the samples of cholesterin were tested at the same time. The results will be found summarised in Tables I. and II. Table I. shows that the cholesterins tested may, according to their action, be divided into three groups: Group I. comprises the four Kahlbaum cholesterins and that of my own making; Group II., which had a rather

---

* A number of sera, kept in a frozen state and examined on various days (up to 30–40 times), gave practically identical values on each examination.

† The W.R. and S.-G.R. were examined and the results of these were still less comparable.

placed in the covered water bath, one in a dry-air incubator, and four in an open water bath. By means of wooden blocks it was arranged that the column of liquid in the tubes of one group was wholly immersed, one was two-thirds immersed, one was half immersed, and one immersed one-third in the water. The result of the experiment will be seen from Table VI., which shows that the weakest reaction took place in the covered water bath; a slightly better result was obtained from the use of the dry-air incubator, there having been some circulation of the liquid in these tubes, produced by the evaporation of the liquid. By being placed in the open water bath, wholly immersed, the reaction is strengthened somewhat, but a really strengthened reaction only appears when the column of liquid in the tubes is only partly immersed in the water. The maximum strength of the reactions was obtained in the tubes where the column of liquid had been *half* immersed; if only one-third of the column of liquid is immersed, the results in some cases are somewhat weaker. It is remarkable that some sera are affected much more than others by this "immersion phenomenon." The average increase of the strength of the reaction is round about 100 per cent.

Inhibition Zones.

In connexion with the experiments described above a number of observations were made which may serve to establish some of the factors which bring about the formation of the so-called inhibition zones. It has previously been observed that some extracts are more apt to give inhibition zones with some sera than others. Apart from the extract, the following factors may influence these formations: (1) The cholesterin; (2) the temperature of inactivation; (3) the temperature at which the reaction is made; (4) circulation of the liquid in the tubes.

That various kinds of cholesterin to various degrees influence the inhibition zone in some sera will be seen from the following examples:—

Cholesterin.	Tube No.—					
	1	2	3	4	5	6
Kahlbaum II. ..	tr	tr÷	t	t	t−	s−
,, III. ..	s−	s÷	t	t	t−	tr÷
,, I. ..	s÷	t	t	t	t−	tr÷

Inactivating serves to remove the inhibition zones which most sera show in active state or after too brief inactivating. If the inactivating is done, however, at too high a temperature (over 54°–55° C.) the inhibition zone returns, as the following examples show:—

—	Tube No.—							
	1	2	3	4	5	6	7	8
Active ..	0	0	tr	tr÷	s	t−	s÷	tr÷
Inactive—								
1½ at 54 C.	s−	t	t	t	t	t	s÷÷	tr
,, 55 ,,	s−	t−	t	t	t	t	s÷÷	tr
,, 56 ,,	0	tr−	t	t	t	t−	s÷	tr−
,, 57 ,,	0	0	tr	t−	t	t−	s−	tr!

That the temperature at which the reaction is carried out plays an important part in the formation of inhibition zones appears from the following:—

Temp. (C.)	Tube No.—						
	1	2	3	4	5	6	7
35°	0	tr−	tr	tr	tr−	tr−	
36°	tr−	tr	tr÷	t−	tr÷	tr!	
37°	tr−	tr÷	t−	t	t÷	s−	tr!
38°	tr	tr÷	t−	t	t−	s(−)	tr!
39°	tr÷	s−	t	t	t−	s(−)	tr!

Temp. (C.)	Tube No.—							
	1	2	3	4	5	6	7	8
35°	tr−	tr−	tr−	s÷	s−	tr		
37°	tr÷	s÷	t	t	t	t	t−	s−
41·5°	t	t	t	t	t	t	t−	s−

These examples show that the very marked inhibition zone at 35° and 36° C. gradually disappears with increasing temperature and at 39°–41·5° has quite disappeared. This makes it probable that the enormous reduction of the reactive capacity which takes place when the temperature sinks from 37° to 35° is principally due to the formation of an inhibition zone which totally masks the reaction and only produces in a lesser degree a real decrease in the velocity of the reaction.

The importance of a strong circulation in the tubes (adjustment of the water level in the water bath) appears from the following:—

—	Tube No.—					
	1	2	3	4	5	6
Water bath, closed ..	0	tr÷	s÷	s	tr	
Dry-air incubator ..	0	tr÷	t−	s÷	tr÷	
Water bath, open—						
1/1 immersed ..	tr÷	s÷	t−	t−	s−	tr?
2/3 ,, ...	s÷	t	t	t−	s÷	tr
1/2 ,, ...	t	t	t	t	s÷	tr

Conclusions.

1. Various specimens of cholesterins, even from the same makers, are not identical with regard to their ability to strengthen the S.R.

2. Inactivation of sera for the S.R. in tubes closed with rubber or cork or sealed in the flame may sometimes bring about some weakening of the reaction. In the case of the S.-G.R. this could not be established.

3. Even slight variations in the temperature at which inactivation is carried out will influence the strength of both the S.R. and the S.-G.R. The rate of the weakening of the strength of the serum is greatly increased for every degree that the temperature is raised above 54° C.

4. When the S.R. is carried out in a closed water bath, a much weaker reaction is obtained than when an open water bath is used.

5. Fluctuations in the temperature at which the S.R. and S.-G.R. are made have a very great influence upon the result of the reaction. In the case of the S.R., temperatures *below* 37° C. are fatal; in the S.-G.R., the same is the case with temperatures *above* 37·5° C.

6. It is of the greatest importance that the adjustment of the water-level in the water bath, so strongly emphasised by Dreyer and Ward, should be exactly adhered to.

7. A number of different factors can give rise to the formation of inhibition zones.

} more strongly in the open than in the covered bath.
15 ,, ,, positively (1·6–2·8 units) in the open bath and negatively in the covered bath.

Thus, about 84 per cent. of the sera tested reacted more strongly in the open than in the covered water bath. The difference was so great (in 36 per cent. of the cases more than 100 per cent.) that this alone can explain the rather poor result obtained with the S.R. during the conference in Copenhagen in 1923.

As to the cause of the phenomenon it is impossible to say anything definite, but the explanation is probably the increase in the degree of flocculation (from tr to t) which occurs on placing the reaction an an open water bath, in contrast to a covered water bath, as the result of an increased circulation of the liquid in the tubes. This again is governed by the difference between the temperature of the water bath and the temperature of the air, measured at the height of the upper edge of the liquid in the Sigma tubes. The difference between the temperature of the water bath and the temperature of the air above it was taken on a series of days and was ascertained to be 0·2°–0·4° C. for the covered water bath; whereas for the open water bath the temperature of the air fluctuated during the course of the 24 hours between 22° and 30°, so that the difference here amounted to 8°–15°. The temperature of the liquid in the tubes was about 37°.

5. *Fluctuations in the Temperature at which the Reaction is Carried Out.*—For both the S.R. and the S.-G.R. the temperature at which the reaction is to be carried out is fixed at 37° C., but it may sometimes happen that external circumstances may produce fluctuations in the temperature of shorter or longer duration, and as there are not, as far as I know, any investigations into the importance of this factor, I felt it might be useful to examine to what degree the reactions in question are sensitive to slight deviations from the prescribed temperature.

(*a*) *Sigma Reaction.*—The course of the reaction was examined at the following temperatures: 35°, 36°, 37°, 38°, 39°, and 41·5° C. For each serum all temperatures were examined simultaneously. The results are summarised in Table IV., and it will be seen that the S.R. is extremely sensitive to even very slight fluctuations in temperature.

TABLE IV.

Temp. (C.)	Σ units per c.cm. in serum No.—														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
35°	25	2·3	0·9	1·7	8·8	0·7	8·8	4·4	1·4	2·5	0·9	1·8	0·7	1·6	0·7
36°	—	31	28	31	34	16	—	—	—	3·1	2·8	—	1·7	—	1·3
37°	220	76	68	62	50	43	28	16·4	14	7·7	7·7	6·4	3·0	2·3	2·0
38°	—	85	76	72	65	44	—	—	—	8·1	7·7	—	3·4	—	2·2
39°	—	85	81	72	65	44	—	—	—	8·5	7·7	—	3·8	—	2·3
41·5	220	—	—	—	—	—	28	17·2	13	—	—	—	—	2·5	—

The reaction was certainly affected to a very slight degree by rising temperature—indeed, as far as some of the sera were concerned no difference could be shown in the strength of the reaction carried out at temperatures from 37° to 41·5° C.; on the other hand, if the temperature sinks below 37° C. it is quite another matter, as the capacity to react is already considerably weakened at 36° C., and at 35° C. all the sera react very weakly, and a large number not at all. It will also be seen from the table that the various sera are not equally sensitive to fluctuations in the temperature; for instance, Serum No. 3 gives 0·9 units per c.cm. at 35° and 81 units per c.cm. at 39° C., whilst No. 10 gives 2·5 and 8·5 units respectively. At 35° C. spontaneous flocculation often appears (from tr– to tr+), and likewise one often comes across several consecutive tubes with the same rather weak precipitation (inhibition zones). The calculation of the strength of the serum in units is in these cases not wholly reliable. As a basis for the calculation the tube which shows the greatest precipitation is always chosen, for instance, 1) 0, 2) tr–, 3) tr+, 4) tr–, 5) tr– = 3·8 units per c.cm.

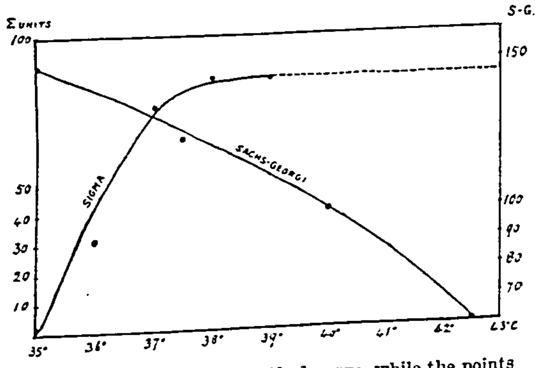
This enormous reduction of the titre of the serum at temperatures below 37° C. is, however, hardly solely due to any real decrease in the speed of the reaction, but rather to the fact that at the low temperatures marked inhibition zones appear so that the reaction is masked, as is seen from some experiments which are described later.

(*b*) *Sachs-Georgi Reaction.*—As it was impossible, the method of quantitative titrating being employed, to observe slight fluctuations in the strength of the reaction, only the following temperatures were tested: 35°, 37·5°, 40°, 42·5° C. All tests were placed in an electrically-heated and regulated incubator, and a control was kept with a maximum and minimum thermometer as to whether the temperature had remained constant during the experiment. The results of the experiment will be found in Table V.,

TABLE V.

Temp. (C.)	Serum No.—														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
35·0°	150	100	40	40	40	30	30	30	30	20	20	15	15	15	15
37·5°	125	100	40	20	30	30	30	30	30	20	20	15	15	12	12
40·0°	100	65	20	10	20	15	20	20	25	10	10	10	5	10	5
42·5°	60	35	10	5	10	5	10	7	15	5	5	5	0	5	0

from which it appears that the S.-G.R., in contrast to the S.R., goes well at 35° C., and that an increase of the temperature from 35° to 37·5° C. in some cases causes a slight weakness, but is generally without influence; if the temperature is raised from 37·5° to 40° C., this causes a considerable decrease in the strength of reaction, and this grows with increasing rapidity with every degree by which the temperature rises; at 42·5° C. most of the sera react negatively, or only slightly positively (±with 0·1 c.cm. serum). The S.R. and the S.-G.R. are thus both influenced by fluctuations in the temperature, but in diametrically opposite directions, as is clearly shown by the graph. What the cause of this may be has not yet been determined.



The lines represent the smoothed curve, while the points represent the actual observations.

6. *Immersion of Sigma Tubes in the Water Bath.*—Dreyer and Ward state in their paper that it is very important to arrange the level of the water in the bath so that not more than the lower half to two-thirds of the column of fluid in the tubes is immersed. But perhaps it might be of interest to determine the exact importance of this point. Of a number of sera several sets were pipetted, one of which was

placed in the covered water bath, one in a dry-air incubator, and four in an open water bath. By means of wooden blocks it was arranged that the column of liquid in the tubes of one group was wholly immersed, one was two-thirds immersed, one was half immersed, and one immersed one-third in the water. The result of the experiment will be seen from Table VI., which shows that the weakest reaction took place in the covered water bath; a slightly better result was obtained from the use of the dry-air incubator, there having been some circulation of the liquid in these tubes, produced by the evaporation of the liquid. By being placed in the open water bath, wholly immersed, the reaction is strengthened somewhat, but a really strengthened reaction only appears when the column of liquid in the tubes is only partly immersed in the water. The maximum strength of the reactions was obtained in the tubes where the column of liquid had been *half* immersed; if only one-third of the column of liquid is immersed, the results in some cases are somewhat weaker. It is remarkable that some sera are affected much more than others by this "immersion phenomenon." The average increase of the strength of the reaction is round about 100 per cent.

Inhibition Zones.

In connexion with the experiments described above a number of observations were made which may serve to establish some of the factors which bring about the formation of the so-called inhibition zones. It has previously been observed that some extracts are more apt to give inhibition zones with some sera than others. Apart from the extract, the following factors may influence these formations: (1) The cholesterin; (2) the temperature of inactivation; (3) the temperature at which the reaction is made; (4) circulation of the liquid in the tubes.

That various kinds of cholesterin to various degrees influence the inhibition zone in some sera will be seen from the following examples:—

Cholesterin.	Tube No.—					
	1	2	3	4	5	6
Kahlbaum II. ..	tr	tr +	t	t	t −	s −
,, III. ..	s −	s +	t	t	t −	tr +
,, I. ..	s +	t	t	t	t −	tr +

Inactivating serves to remove the inhibition zones which most sera show in active state or after too brief inactivating. If the inactivating is done, however, at too high a temperature (over 54°–55° C.) the inhibition zone returns, as the following examples show:—

—	Tube No.—							
	1	2	3	4	5	6	7	8
Active ..	0	0	tr	tr +	s	t −	s +	tr +
Inactive—								
1½ at 54 C.	s +	t	t	t	t	t	s + +	tr
,, 55 ,,	s −	t −	t	t	t	t	s + +	tr
,, 56 ,,	0	tr +	t	t	t	t −	s +	tr −
,, 57 ,,	0	0	tr	t −	t	t −	s −	tr?

That the temperature at which the reaction is carried out plays an important part in the formation of inhibition zones appears from the following:—

Temp. (C.)	Tube No.—						
	1	2	3	4	5	6	7
35°	0	tr −	tr	tr	tr −	tr −	
36°	tr −	tr	tr +	t −	tr +	tr?	
37°	tr −	tr +	t −	t	t +	s −	tr?
38°	tr	tr +	t −	t	t −	s(−)	tr?
39°	tr +	s −	t	t	t −	s(−)	tr?

Temp. (C.)	Tube No.—							
	1	2	3	4	5	6	7	8
35°	tr −	tr −	tr −	s +	s −	tr		
37°	tr +	s +	t	t	t	t	t −	s −
41·5°	t	t	t	t	t	t	t −	s −

These examples show that the very marked inhibition zone at 35° and 36° C. gradually disappears with increasing temperature and at 39°–41·5° has quite disappeared. This makes it probable that the enormous reduction of the reactive capacity which takes place when the temperature sinks from 37° to 35° is principally due to the formation of an inhibition zone which totally masks the reaction and only produces in a lesser degree a real decrease in the velocity of the reaction.

The importance of a strong circulation in the tubes (adjustment of the water level in the water bath) appears from the following:—

—	Tube No.—					
	1	2	3	4	5	6
Water bath, closed ..	0	tr +	s +	s	tr	
Dry-air incubator ..	0	tr +	t −	s +	tr +	
Water bath, open—						
1/1 immersed ..	tr +	s +	t −	t −	s −	tr?
2/3 ,, ...	s +	t	t	t −	s +	tr
1/2 ,, ...	t	t	t	t	s +	tr

Conclusions.

1. Various specimens of cholesterins, even from the same makers, are not identical with regard to their ability to strengthen the S.R.

2. Inactivation of sera for the S.R. in tubes closed with rubber or cork or sealed in the flame may sometimes bring about some weakening of the reaction. In the case of the S.-G.R. this could not be established.

3. Even slight variations in the temperature at which inactivation is carried out will influence the strength of both the S.R. and the S.-G.R. The rate of the weakening of the strength of the serum is greatly increased for every degree that the temperature is raised above 54° C.

4. When the S.R. is carried out in a closed water bath, a much weaker reaction is obtained than when an open water bath is used.

5. Fluctuations in the temperature at which the S.R. and S.-G.R. are made have a very great influence upon the result of the reaction. In the case of the S.R., temperatures *below* 37° C. are fatal; in the S.-G.R., the same is the case with temperatures *above* 37·5° C.

6. It is of the greatest importance that the adjustment of the water-level in the water bath, so strongly emphasised by Dreyer and Ward, should be exactly adhered to.

7. A number of different factors can give rise to the formation of inhibition zones.

was submerged in the water. Altogether, 110 sera were tested in this manner. The result was that—

18 sera reacted equally in both water baths.
3 ,, ,, 0–10 %
9 ,, ,, 10–25 %
11 ,, ,, 25–50 %
29 ,, ,, 50–100 % more strongly in the open than in the covered bath.
19 ,, ,, 100–200 %
4 ,, ,, 200–400 %
2 ,, ,, 500 %
15 ,, ,, positively (1·6–2·8 units) in the open bath and negatively in the covered bath.

Thus, about 84 per cent. of the sera tested reacted more strongly in the open than in the covered water bath. The difference was so great (in 36 per cent. of the cases more than 100 per cent.) that this alone can explain the rather poor result obtained with the S.R. during the conference in Copenhagen in 1923.

As to the cause of the phenomenon it is impossible to say anything definite, but the explanation is probably the increase in the degree of flocculation (from tr to t) which occurs on placing the reaction an an open water bath, in contrast to a covered water bath, as the result of an increased circulation of the liquid in the tubes. This again is governed by the difference between the temperature of the water bath and the temperature of the air, measured at the height of the upper edge of the liquid in the Sigma tubes. The difference between the temperature of the water bath and the temperature of the air above it was taken on a series of days and was ascertained to be 0·2°–0·4° C. for the covered water bath; whereas for the open water bath the temperature of the air fluctuated during the course of the 24 hours between 22° and 30°, so that the difference here amounted to 8°–15°. The temperature of the liquid in the tubes was about 37°.

5. *Fluctuations in the Temperature at which the Reaction is Carried Out.*—For both the S.R. and the S.-G.R. the temperature at which the reaction is to be carried out is fixed at 37° C., but it may sometimes happen that external circumstances may produce fluctuations in the temperature of shorter or longer duration, and as there are not, as far as I know, any investigations into the importance of this factor, I felt it might be useful to examine to what degree the reactions in question are sensitive to slight deviations from the prescribed temperature.

(*a*) *Sigma Reaction.*—The course of the reaction was examined at the following temperatures: 35°, 36°, 37°, 38°, 39°, and 41·5° C. For each serum all temperatures were examined simultaneously. The results are summarised in Table IV., and it will be seen that the S.R. is extremely sensitive to even very slight fluctuations in temperature.

TABLE IV.

Temp. (C.)	Σ units per c.cm. in serum No.—

The reaction was certainly affected to a very slight degree by rising temperature—indeed, as far as some of the sera were concerned no difference could be shown in the strength of the reaction carried out at temperatures from 37° to 41·5° C.; on the other hand, if the temperature sinks below 37° C. it is quite another matter, as the capacity to react is already considerably weakened at 36° C., and at 35° C. all the sera react very weakly, and a large number not at all. It will also be seen from the table that the various sera are not equally sensitive to fluctuations in the temperature; for instance, Serum No. 3 gives 0·9 units per c.cm. at 35° and 81 units per c.cm. at 39° C., whilst No. 10 gives 2·5 and 8·5 units respectively. At 35° C. spontaneous flocculation often appears (from tr− to tr+), and likewise one often comes across several consecutive tubes with the same rather weak precipitation (inhibition zones). The calculation of the strength of the serum in units is in these cases not wholly reliable. As a basis for the calculation the tube which shows the greatest precipitation is always chosen, for instance, 1) 0, 2) tr−, 3) tr+, 4) tr−, 5) tr− = 3·8 units per c.cm.

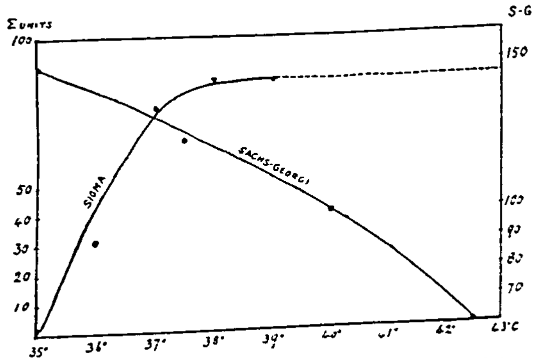
This enormous reduction of the titre of the serum at temperatures below 37° C. is, however, hardly solely due to any real decrease in the speed of the reaction, but rather to the fact that at the low temperatures marked inhibition zones appear so that the reaction is masked, as is seen from some experiments which are described later.

(*b*) *Sachs-Georgi Reaction.*—As it was impossible, the method of quantitative titrating being employed, to observe slight fluctuations in the strength of the reaction, only the following temperatures were tested: 35°, 37·5°, 40°, 42·5° C. All tests were placed in an electrically-heated and regulated incubator, and a control was kept with a maximum and minimum thermometer as to whether the temperature had remained constant during the experiment. The results of the experiment will be found in Table V.,

TABLE V.

Temp. (C.)	Serum No.—														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
35·0°	150	100	40	40	40	30	30	30	30	20	20	15	15	15	15
37·5°	125	100	40	20	30	30	30	30	30	20	20	15	15	12	12
40·0°	100	65	20	10	20	15	20	20	25	10	10	10	5	10	5
42·5°	60	35	10	5	10	5	10	7	15	5	5	5	0	5	0

from which it appears that the S.-G.R., in contrast to the S.R., goes well at 35° C., and that an increase of the temperature from 35° to 37·5° C. in some cases causes a slight weakness, but is generally without influence; if the temperature is raised from 37·5° to 40° C., this causes a considerable decrease in the strength of reaction, and this grows with increasing rapidity with every degree by which the temperature rises; at 42·5° C. most of the sera react negatively, or only slightly positively (±with 0·1 c.cm. serum). The S.R. and the S.-G.R. are thus both influenced by fluctuations in the temperature, but in diametrically opposite directions, as is clearly shown by the graph. What the cause of this may be has not yet been determined.



The lines represent the smoothed curve, while the points represent the actual observations.

6. *Immersion of Sigma Tubes in the Water Bath.*—Dreyer and Ward state in their paper that it is very important to arrange the level of the water in the bath so that not more than the lower half to two-thirds of the column of fluid in the tubes is immersed. But perhaps it might be of interest to determine the exact importance of this point. Of a number of sera several sets were pipetted, one of which was

placed in the covered water bath, one in a dry-air incubator, and four in an open water bath. By means of wooden blocks it was arranged that the column of liquid in the tubes of one group was wholly immersed, one was two-thirds immersed, one was half immersed, and one immersed one-third in the water. The result of the experiment will be seen from Table VI., which shows that the weakest reaction took place in the covered water bath; a slightly better result was obtained from the use of the dry-air incubator, there having been some circulation of the liquid in these tubes, produced by the evaporation of the liquid. By being placed in the open water bath, wholly immersed, the reaction is strengthened somewhat, but a really strengthened reaction only appears when the column of liquid in the tubes is only partly immersed in the water. The maximum strength of the reactions was obtained in the tubes where the column of liquid had been *half* immersed; if only one-third of the column of liquid is immersed, the results in some cases are somewhat weaker. It is remarkable that some sera are affected much more than others by this "immersion phenomenon." The average increase of the strength of the reaction is round about 100 per cent.

Inhibition Zones.

In connexion with the experiments described above a number of observations were made which may serve to establish some of the factors which bring about the formation of the so-called inhibition zones. It has previously been observed that some extracts are more apt to give inhibition zones with some sera than others. Apart from the extract, the following factors may influence these formations: (1) The cholesterin; (2) the temperature of inactivation; (3) the temperature at which the reaction is made; (4) circulation of the liquid in the tubes.

That various kinds of cholesterin to various degrees influence the inhibition zone in some sera will be seen from the following examples:—

Cholesterin.	Tube No.—					
	1	2	3	4	5	6
Kahlbaum II. ..	tr	tr ÷	t	t	t −	s −
,, III. ..	s −	s ÷	t	t	t −	tr +
,, I. ..	s ÷	t	t	t	t −	tr ÷

Inactivating serves to remove the inhibition zones which most sera show in active state or after too brief inactivating. If the inactivating is done, however, at too high a temperature (over 54°–55° C.) the inhibition zone returns, as the following examples show:—

—	Tube No.—							
	1	2	3	4	5	6	7	8
Active ..	0	0	tr	tr ÷	s	t −	s ÷	tr ÷
Inactive—								
1½ at 54° C.	s ÷	t	t	t	t	t	s ÷ ÷	tr
,, 55 ..	s −	t −	t	t	t	t	s ÷ ÷	tr
,, 56 ..	0	tr ÷	t	t	t	t −	s ÷	tr −
,, 57 ..	0	0	tr	t −	t	t −	s −	tr?

That the temperature at which the reaction is carried out plays an important part in the formation of inhibition zones appears from the following:—

Temp. (C.)	Tube No.—						
	1	2	3	4	5	6	7
35°	0	tr −	tr	tr	tr −	tr −	
36°	tr −	tr	tr +	t −	tr ÷	tr?	
37°	tr −	tr ÷	t −	t	t ÷	s −	tr?
38°	tr	tr ÷	t −	t	t −	s(−)	tr?
39°	tr ÷	s −	t	t	t −	s(−)	tr?

Temp. (C.)	Tube No.—							
	1	2	3	4	5	6	7	8
35°	tr −	tr −	tr −	s +	s −	tr		
37°	tr ÷	s +	t	t	t	t	t −	s −
41·5°	t	t	t	t	t	t	t −	s −

These examples show that the very marked inhibition zone at 35° and 36° C. gradually disappears with increasing temperature and at 39°–41·5° has quite disappeared. This makes it probable that the enormous reduction of the reactive capacity which takes place when the temperature sinks from 37° to 35° is principally due to the formation of an inhibition zone which totally masks the reaction and only produces in a lesser degree a real decrease in the velocity of the reaction.

The importance of a strong circulation in the tubes (adjustment of the water level in the water bath) appears from the following:—

—	Tube No.—					
	1	2	3	4	5	6
Water bath, closed ..	0	tr ÷	s ÷	s	tr	
Dry-air incubator ..	0	tr ÷	t −	s +	tr ÷	
Water bath, open—						
1/1 immersed ..	tr ÷	s ÷	t −	t −	s −	tr?
2/3 ,, ...	s ÷	t	t	t −	s +	tr
1/2 ,, ...	t	t	t	t	s ÷	tr

Conclusions.

1. Various specimens of cholesterins, even from the same makers, are not identical with regard to their ability to strengthen the S.R.

2. Inactivation of sera for the S.R. in tubes closed with rubber or cork or sealed in the flame may sometimes bring about some weakening of the reaction. In the case of the S.-G.R. this could not be established.

3. Even slight variations in the temperature at which inactivation is carried out will influence the strength of both the S.R. and the S.-G.R. The rate of the weakening of the strength of the serum is greatly increased for every degree that the temperature is raised above 54° C.

4. When the S.R. is carried out in a closed water bath, a much weaker reaction is obtained than when an open water bath is used.

5. Fluctuations in the temperature at which the S.R. and S.-G.R. are made have a very great influence upon the result of the reaction. In the case of the S.R., temperatures *below* 37° C. are fatal; in the S.-G.R., the same is the case with temperatures *above* 37·5° C.

6. It is of the greatest importance that the adjustment of the water-level in the water bath, so strongly emphasised by Dreyer and Ward, should be exactly adhered to.

7. A number of different factors can give rise to the formation of inhibition zones.

was submerged in the water. Altogether, 110 sera were tested in this manner. The result was that—

18 sera reacted equally in both water baths.
3 ,, ,, 0–10 %
9 ,, ,, 10–25 %
11 ,, ,, 25–50 %
29 ,, ,, 50–100 % } more strongly in the open than in the covered bath.
19 ,, ,, 100–200 %
4 ,, ,, 200–400 %
2 ,, ,, 500 %
15 ,, ,, positively (1·6–2·8 units) in the open bath and negatively in the covered bath.

Thus, about 84 per cent. of the sera tested reacted more strongly in the open than in the covered water bath. The difference was so great (in 36 per cent. of the cases more than 100 per cent.) that this alone can explain the rather poor result obtained with the S.R. during the conference in Copenhagen in 1923.

As to the cause of the phenomenon it is impossible to say anything definite, but the explanation is probably the increase in the degree of flocculation (from tr to t) which occurs on placing the reaction an an open water bath, in contrast to a covered water bath, as the result of an increased circulation of the liquid in the tubes. This again is governed by the difference between the temperature of the water bath and the temperature of the air, measured at the height of the upper edge of the liquid in the Sigma tubes. The difference between the temperature of the water bath and the temperature of the air above it was taken on a series of days and was ascertained to be 0·2°–0·4° C. for the covered water bath; whereas for the open water bath the temperature of the air fluctuated during the course of the 24 hours between 22° and 30°, so that the difference here amounted to 8°–15°. The temperature of the liquid in the tubes was about 37°.

5. *Fluctuations in the Temperature at which the Reaction is Carried Out.*—For both the S.R. and the S.-G.R. the temperature at which the reaction is to be carried out is fixed at 37° C., but it may sometimes happen that external circumstances may produce fluctuations in the temperature of shorter or longer duration, and as there are not, as far as I know, any investigations into the importance of this factor, I felt it might be useful to examine to what degree the reactions in question are sensitive to slight deviations from the prescribed temperature.

(*a*) *Sigma Reaction.*—The course of the reaction was examined at the following temperatures: 35°, 36°, 37°, 38°, 39°, and 41·5° C. For each serum all temperatures were examined simultaneously. The results are summarised in Table IV., and it will be seen that the S.R. is extremely sensitive to even very slight fluctuations in temperature.

TABLE IV.

Temp. (C.)	Σ units per c.cm. in serum No.—														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
35°	25	2·3	0·9	1·7	8·8	0·7	8·8	4·4	1·4	2·5	0·9	1·8	0·7	1·6	0·7
36°	—	31	28	31	34	16	—	—	—	3·1	2·8	—	1·7	—	1·3
37°	220	76	68	62	50	43	28	16·4	14	7·7	7·7	6·4	3·0	2·3	2·0
38°	—	85	76	72	65	44	—	—	—	8·1	7·7	—	3·4	—	2·2
39°	—	85	81	72	65	44	—	—	—	8·5	7·7	—	3·8	—	2·3
41 5	220	—	—	—	—	—	28	17·2	13	—	—	—	—	2·5	—

The reaction was certainly affected to a very slight degree by rising temperature—indeed, as far as some of the sera were concerned no difference could be shown in the strength of the reaction carried out at temperatures from 37° to 41·5° C.; on the other hand, if the temperature sinks below 37° C. it is quite another matter, as the capacity to react is already considerably weakened at 36° C., and at 35° C. all the sera react very weakly, and a large number not at all. It will also be seen from the table that the various sera are not equally sensitive to fluctuations in the temperature; for instance, Serum No. 3 gives 0·9 units per c.cm. at 35° and 81 units per c.cm. at 39° C., whilst No. 10 gives 2·5 and 8·5 units respectively. At 35° C. spontaneous flocculation often appears (from tr– to tr+), and likewise one often comes across several consecutive tubes with the same rather weak precipitation (inhibition zones). The calculation of the strength of the serum in units is in these cases not wholly reliable. As a basis for the calculation the tube which shows the greatest precipitation is always chosen, for instance, 1) 0, 2) tr–, 3) tr+, 4) tr–, 5) tr– = 3·8 units per c.cm.

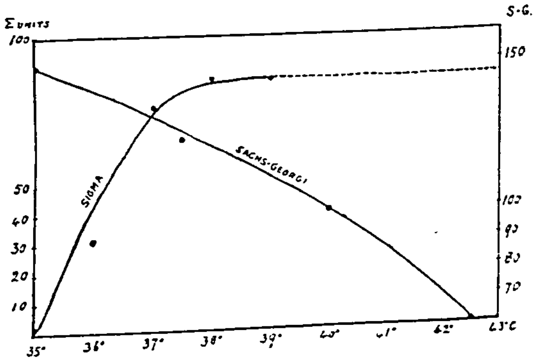
This enormous reduction of the titre of the serum at temperatures below 37° C. is, however, hardly solely due to any real decrease in the speed of the reaction, but rather to the fact that at the low temperatures marked inhibition zones appear so that the reaction is masked, as is seen from some experiments which are described later.

(*b*) *Sachs-Georgi Reaction.*—As it was impossible, the method of quantitative titrating being employed, to observe slight fluctuations in the strength of the reaction, only the following temperatures were tested: 35°, 37·5°, 40°, 42·5° C. All tests were placed in an electrically-heated and regulated incubator, and a control was kept with a maximum and minimum thermometer as to whether the temperature had remained constant during the experiment. The results of the experiment will be found in Table V.,

TABLE V.

Temp. (C.)	Serum No.—														
	1	2	3	4	5	6	7	8	9	10	11	12	13	11	15
35·0°	150	100	40	40	40	30	30	30	30	20	20	15	15	15	15
37·5°	125	100	40	20	30	30	30	30	30	20	20	15	15	12	12
40·0°	100	65	20	10	20	15	20	20	25	10	10	10	5	10	5
42·5°	60	35	10	5	10	5	10	7	15	5	5	5	0	5	0

from which it appears that the S.-G.R., in contrast to the S.R., goes well at 35° C., and that an increase of the temperature from 35° to 37·5° C. in some cases causes a slight weakness, but is generally without influence; if the temperature is raised from 37·5° to 40° C., this causes a considerable decrease in the strength of reaction, and this grows with increasing rapidity with every degree by which the temperature rises; at 42·5° C. most of the sera react negatively, or only slightly positively (±with 0·1 c.cm. serum). The S.R. and the S.-G.R. are thus both influenced by fluctuations in the temperature, but in diametrically opposite directions, as is clearly shown by the graph. What the cause of this may be has not yet been determined.



The lines represent the smoothed curve, while the points represent the actual observations.

6. *Immersion of Sigma Tubes in the Water Bath.*—Dreyer and Ward state in their paper that it is very important to arrange the level of the water in the bath so that not more than the lower half to two-thirds of the column of fluid in the tubes is immersed. But perhaps it might be of interest to determine the exact importance of this point. Of a number of sera several sets were pipetted, one of which was

placed in the covered water bath, one in a dry-air incubator, and four in an open water bath. By means of wooden blocks it was arranged that the column of liquid in the tubes of one group was wholly immersed, one was two-thirds immersed, one was half immersed, and one immersed one-third in the water. The result of the experiment will be seen from Table VI., which shows that the weakest reaction took place in the covered water bath; a slightly better result was obtained from the use of the dry-air incubator, there having been some circulation of the liquid in these tubes, produced by the evaporation of the liquid. By being placed in the open water bath, wholly immersed, the reaction is strengthened somewhat, but a really strengthened reaction only appears when the column of liquid in the tubes is only partly immersed in the water. The maximum strength of the reactions was obtained in the tubes where the column of liquid had been *half* immersed; if only one-third of the column of liquid is immersed, the results in some cases are somewhat weaker. It is remarkable that some sera are affected much more than others by this "immersion phenomenon." The average increase of the strength of the reaction is round about 100 per cent.

TABLE VI.

Inhibition Zones.

In connexion with the experiments described above a number of observations were made which may serve to establish some of the factors which bring about the formation of the so-called inhibition zones. It has previously been observed that some extracts are more apt to give inhibition zones with some sera than others. Apart from the extract, the following factors may influence these formations: (1) The cholesterin; (2) the temperature of inactivation; (3) the temperature at which the reaction is made; (4) circulation of the liquid in the tubes.

That various kinds of cholesterin to various degrees influence the inhibition zone in some sera will be seen from the following examples:—

Cholesterin.	Tube No.—					
	1	2	3	4	5	6
Kahlbaum II. ..	tr	tr +	t	t	t −	s −
,, III. ..	s −	s +	t	t	t −	tr +
,, I. ..	s +	t	t	t	t −	tr +

Inactivating serves to remove the inhibition zones which most sera show in active state or after too brief inactivating. If the inactivating is done, however, at too high a temperature (over 54°–55° C.) the inhibition zone returns, as the following examples show:—

—	Tube No.—							
	1	2	3	4	5	6	7	8
Active ..	0	0	tr	tr +	s	t −	s +	tr +
Inactive—								
1½ at 54° C.	s +	t	t	t	t	t	s + +	tr
,, 55 ,,	s −	t −	t	t	t	t	s + +	tr
,, 56 ,,	0	tr +	t	t	t	t −	s +	tr −
,, 57 ,,	0	0	tr	t −	t	t −	s −	tr?

That the temperature at which the reaction is carried out plays an important part in the formation of inhibition zones appears from the following:—

Temp. (C.)	Tube No.—						
	1	2	3	4	5	6	7
35°	0	tr −	tr	tr	tr −	tr −	
36°	tr −	tr	tr +	t −	tr +	tr?	
37°	tr −	tr +	t −	t	t +	s −	tr?
38°	tr	tr +	t −	t	t −	s(−)	tr?
39°	tr +	s −	t	t	t −	s(−)	tr?

Temp. (C.)	Tube No.—							
	1	2	3	4	5	6	7	8
35°	tr −	tr −	tr −	s +	s −	tr		
37°	tr +	s +	t	t	t	t	t −	s −
41·5°	t	t	t	t	t	t	t −	s −

These examples show that the very marked inhibition zone at 35° and 36° C. gradually disappears with increasing temperature and at 39°–41·5° has quite disappeared. This makes it probable that the enormous reduction of the reactive capacity which takes place when the temperature sinks from 37° to 35° is principally due to the formation of an inhibition zone which totally masks the reaction and only produces in a lesser degree a real decrease in the velocity of the reaction.

The importance of a strong circulation in the tubes (adjustment of the water level in the water bath) appears from the following:—

—	Tube No.—					
	1	2	3	4	5	6
Water bath, closed ..	0	tr +	s +	s	tr	
Dry-air incubator ..	0	tr +	t −	s +	tr +	
Water bath, open—						
1/1 immersed ..	tr +	s +	t −	t −	s −	tr?
2/3 ,, ...	s +	t	t	t −	s +	tr
1/2 ,, ...	t	t	t	t	s +	tr

Conclusions.

1. Various specimens of cholesterins, even from the same makers, are not identical with regard to their ability to strengthen the S.R.

2. Inactivation of sera for the S.R. in tubes closed with rubber or cork or sealed in the flame may sometimes bring about some weakening of the reaction. In the case of the S.-G.R. this could not be established.

3. Even slight variations in the temperature at which inactivation is carried out will influence the strength of both the S.R. and the S.-G.R. The rate of the weakening of the strength of the serum is greatly increased for every degree that the temperature is raised above 54° C.

4. When the S.R. is carried out in a closed water bath, a much weaker reaction is obtained than when an open water bath is used.

5. Fluctuations in the temperature at which the S.R. and S.-G.R. are made have a very great influence upon the result of the reaction. In the case of the S.R., temperatures *below* 37° C. are fatal; in the S.-G.R., the same is the case with temperatures *above* 37·5° C.

6. It is of the greatest importance that the adjustment of the water-level in the water bath, so strongly emphasised by Dreyer and Ward, should be exactly adhered to.

7. A number of different factors can give rise to the formation of inhibition zones.

ON AN IMPROVED PROPHYLACTIC METHOD OF TREATMENT OF ECLAMPSIA.[1]

BY PROF. B. B. STROGANOFF,
LENINGRAD.

AT the Battle of Trafalgar the British navy lost 1690 men, killed and wounded, whereas, according to Thomas Watts Eden, during the period of ten years from 1910 to 1920 there died through eclampsia in Great Britain and Ireland on the average 630 mothers per annum (22·5 per cent. of the cases) and double this number of children (47·8 per cent.). In other words, the loss of human lives during this period from eclampsia was higher than in that great battle.

It appears that in America the mortality from eclampsia is still greater. Leighton states that the death-rate in nine of the chief gynæcological institutions for five years reached 38·4 per cent. Rickets states that in U.S.A. 4000 mothers die annually of eclampsia, whilst, according to Coles Stricker, the average number of cases in that country amounts to 7500 per annum. If these figures are correct, the mortality reaches the enormous figure of 53·5 per cent. Hammerschlag also points out that the mortality from eclampsia in the United States is higher than in Europe. Whereas, in Paris, Berlin, Budapest, and Milan the mortality from eclampsia was about 1 to each 1000 deaths amongst women, in Chicago the proportion was 1·9, in San Francisco 2·9, and in New Orleans even 6·4 among the whites and 3·4 among the coloured population. There is reason to believe that the application of the improved prophylactic method of treatment of this disease will diminish the mortality by at least half.

History of the Method.

I first applied the method detailed later in 1897 and had no deaths from eclampsia in the first 57 cases. At the International Congresses in Paris (1900) and in Rome (1902) I reported 92 and 126 cases of eclampsia respectively with a mortality of 5 to 6 per cent. In 1907 I visited Rosthorn's clinic in Heidelberg and successfully treated a case who had had 11 fits in the course of 9½ hours and coma, with a pulse-rate of 150. Excellent results were obtained by me in 1909 in the clinics of Profs. Schauta and Piscacek (in Vienna), and in 1911 in the clinics of Profs. Bumm and Franz (Berlin). In 1908 I was able to report on 360 cases of eclampsia with a maternal mortality of 6·6 per cent. and a child mortality of 21·6 per cent. (the latter being eclampsias sub partu). Prof. Leopold, in Dresden, first applied my method in 1909, and obtained excellent results on 50 patients, out of which only four with complications died; 34 per cent. had no fits from the moment when treatment began, whilst 50 per cent. had only one to three fits.

The second to adopt my method in Germany was Prof. Krönig in Freiburg, whose five cases of eclampsia were completely satisfactory both as regards the mothers and the children. Since then this method spread further in Germany, in Switzerland (Herff), in Holland (Mingelen), in Sweden (Forssner), and even in the far Argentine (Enricque Zarate).

In 1918 I was able to collect from the literature—which is far from complete—2208 cases of eclampsia treated by this method and its variations, with a total maternal mortality of 9·8 per cent. Amongst 878 children born from eclamptic mothers, whose history is recorded, the mortality after treatment by this method was about 12 per cent. lower than in cases treated by other methods in the same clinics. Acting on behalf of Prof. Hinselmann, Dr. Weinsenfels discovered 1094 more cases up to 1924, which raises the number of cases to *3302, of which 357—i.e., 10·8 per cent.—terminated fatally.*

Still better results were obtained by us during the last 10–12 years after the method was somewhat modified. Out of 253 cases of eclampsia with fits at the State Clinical Institute of Obstetrics and Gynæcology (during 9½ years), and the Krassovsky Lying-in Hospital (from 1910 to 1921, when it was closed) only six deaths—i.e., 2·4 per cent.—were observed. In three of these cases we were dealing with hopeless patients. In one case we were unable to apply the prophylactic treatment in the absence of chloral hydrate, and in two cases of relatively light eclampsia death resulted from pneumonia and septicæmia. Thus, we had not a single death from eclampsia in cases that had not been neglected, and obtained figures regarding which Dr. Fürst[2] justly remarks: "In the statistics of the whole literature these favourable results stand out unsurpassed."

The Secondary Effects of the Treatment.

The beneficent effect of this treatment is confirmed by a series of other facts.

Thus, (1) *the number of fits diminished markedly.* In the course of the last ten years we obtained immediate cessation of the fits after the treatment was commenced in 40 per cent. of cases. In 45 per cent. the fits were repeated from one to three times, and only in 15 per cent. they were more numerous.

(2) *There is a large number of "intercurrent" eclampsias—i.e., cases in which there is freedom from fits for 12 hours and more before delivery.* Formerly, there were from 21 to 27 per cent. of such cases in prophylactic treatment. In the last group treated they amounted to 40·9 per cent. These figures do not, however, sufficiently characterise the power of the method in checking the fits, since many eclamptic patients are delivered in less than 12 hours after cessation of the fits. The efficacy of the method is more distinctly exhibited in cases of eclampsia sub graviditate; since 1916 66 per cent. of such eclampsias manifested an intercurrent course. This is a great advantage, since the pregnancy progresses after cessation of the fits and the child is delivered mature.

(3) *Psychical disturbances* are few in number and of a mild character. Out of 253 cases of eclampsia there were only four—i.e., 1·6 per cent. In one case the patient had five fits and after delivery suffered from nephritis, when mild symptoms of psychosis were observed for some days. In another patient, who had only one fit sub graviditate in the post-partum period, symptoms of icterus gravis were observed, in connexion with which psychosis was observed for several days. Recovery followed.

(4) *The mortality of children is relatively favourable.* For the whole group it amounts to 14·3 per cent., for eclampsia sub partu et sub graviditate 20 per cent., and for post-partum cases 6·2 per cent. The most interesting group for us are the eclampsias ante partum and intra-partum, since in these the action of the drugs upon the fœtus is manifested. The mortality in this group was 20·1 per cent., but if the premature children (weighing less than 2000 g.), which died before treatment was commenced, from cold, operation, &c., are excluded, there remain only 6 per cent. attributable to eclampsia and treatment. And since 6·2 per cent. of fœtuses also perished in post-partum eclampsias, very little remains to the share of drugs.

(5) For the whole group of 253 eclampsias there was not a single death of the mother due to treatment. As is known, in the method of treatment of eclampsia by forced delivery some mothers die as the result of operation. In Bumm and Franz's cases about 4 per cent. of women died in consequence of operation.

(6) Diminution in the number of operative deliveries. These amounted to 56 per cent.

(7) Few cases of pneumonia.—4 in 253 patients.

(8) Rapid recovery of the patients.

On the basis of these 253 eclampsias, as well as of the analysis of the preceding 570 cases treated by the less perfect variety of the prophylactic method, I have arrived at the conclusion that a favourable prognosis can be given for the mother in cases of eclampsia that have not been neglected.

---

[1] Being a paper read at the Section of Obstetrics and Gynæcology of the Royal Society of Medicine on July 3rd, 1924.

[2] Zentralbl. f. gynäk., 1924, No. 16, 843.

An extremely interesting confirmation of this is presented by the immense monograph on eclampsia by Prof. Hinselmann, of Bonn, in collaboration with 12 other specialists. He praises highly the great efficiency of this method, and points out that if my figures are achieved by others using my method the problem of the treatment of eclampsia may be regarded as solved. One may hope that the British and American cases of eclampsia are not more intractable than the Russian and German ones.

Proposals for trial in England.

I would like to verify the method in this country and possibly improve the details; at the same time it is my desire to collect the 47 cases to make up a total of 300 treated by this method.

1. The first condition necessary for a trial of my method would be to give me the opportunity of taking part in the treatment of as many cases of eclampsia occurring during the next 1½–2 months of my sojourn in London, as possible. The authorities could perhaps select four or five lying-in institutions in London and request their directors to provide me with the necessary material. It is important to provide for this purpose a separate hygienic room.

2. The exact application of the method is only possible with the help of an experienced qualified assistant who has a knowledge of the method. It is also necessary to have a midwife capable of looking after the eclamptic patient according to the requirements of the method. If a nurse is available, she also should be instructed accordingly. If it were possible to choose these persons beforehand, I would speak to them and instruct them in the technical part of the process. Of course, it is important to have the necessary medicaments and instruments always ready (morphine, chloral, chloroform, oxygen, digitalis, instruments for venesection and for delivery).

3. I consider the demand of T. W. Eden that eclampsias should be classified as mild, severe, and moribund to be very important. To the seven features by which he characterises the severe cases I would add the following two—nephritis of long duration and fits recurring four or more times during two hours. It would seem to me desirable to establish another category of severe cases; those manifesting two-thirds of the symptoms of severity should be referred to as morituræ, or very severe cases, with an additional symptom—*presence of cerebral hæmorrhage.*

4. Considering the importance of this experiment not only in England but in all civilised countries, it would be desirable to establish a special committee for the exact estimation and observation of the cases. Such a committee would naturally be composed of the directors of the lying-in departments of the coöperating institutions, presided over by a person selected by the Section of Obstetrics and Gynæcology of the Royal Society of Medicine.

I am prepared to present myself to take part in the treatment of cases by day and by night.

The Scheme of the Method.

The following is the brief scheme of the method of treatment which is more fully described elsewhere.[3]

Eclamptic patients in most cases die from the destructive action of the fits upon the heart, respiratory centre, &c. Therefore the fits must be repressed. Eclampsias sub graviditate and eclampsias sub partu are treated with equal energy. Post-partum eclampsias have a milder course, and therefore in most cases require the administration of smaller doses of narcotics. Sometimes they are extremely severe and then require maximum doses. During the fits the patient should be protected against injuries, the tongue protected against bites, and oxygen should be given after fits to remove asphyxia. Chloroform is harmful in typical fits, but if the patient is breathing (clonic convulsions) it is useful.

1. *Removal of all irritations:* (*a*) All noise to be eliminated, (*b*) room darkened, (*c*) examinations reduced to a minimum, (*d*) if possible, separate room and constant observation. Transfer to room under chloroform.

2. *Administration of narcotics:* Morphine and chloral hydrate according to scheme below.

The beginning of treatment: ¼ gr. (⅙–⅓ gr.) morph. hyd. hypodermically. 1 hour: 30 gr. (38–22 gr.) chlor. hydr. per os or per rectum. 3 hours from the beginning of the treatment: from ¼ gr. (⅙–⅓ gr.) morph. hyd. hypodermically. 7 hours: As at 1 hour. 13 hours: 22 gr. (15–30 gr.) chlor. hydr. 21 hours: 22 gr. (15–30 gr.) chlor. hydr. Dose increased in severe eclampsia in the case of strong individuals, and diminished in mild forms. When patient is conscious chloral hydrate is introduced per os, and in unconscious condition per rectum with milk and physiological salt solution. During the first two intervals we *frequently administer* chloroform 10–20 minims in the presence of prodromata of a fit. On the second day undelivered patients receive 15–22 gr. chlor. hydr. t.i.d. In the absence of fits during 14 hours and when the patient is in good condition the dosage may be diminished.

3. If the fit recurs *two to three times*, or even once in severe form, in spite of administration of morphine and chloral hydrate, it is necessary to perform venesection, drawing off 400 c.cm. of blood. This is not resorted to if delivery is expected within the next 1–2 hours.

4. As soon as the eclamptic patient can be delivered without harm to herself and child, delivery is undertaken, either with forceps, by extraction, or rarely, by version. In the absence of contra-indications we rupture the bag of membranes, if the os has dilated to two fingers in a multipara, and about three fingers in a primipara.

5. *Maintenance of regular functions of chief organs*:—

(*a*) Kidneys and skin: Patient kept warm with hot water bottles at the feet and in the region of the kidneys; hot tea diluted with milk should be given; unconscious patients must have milk and physiological salt solution āā (about 1000 c.c. per diem), usually with chloral hydrate, per rectum.

(*b*) Lungs: Oxygen after a fit, pure warm air, removal of all hindrances to respiratory movements: unconscious eclamptic patients should be kept chiefly on the right side; careful cleansing of the mouth and nose from mucus, blood, and vomited matter.

(*c*) Heart: Administration of fluids (see (*a*)), when weakened after numerous fits—digitalis (if the pulse-rate is 110 or higher)—and when the heart is still weaker—camphor, caffein. Patients admitted from outside after six or more fits immediately undergo narcotic treatment and venesection. Continuous observation of patient and child during the first 24 hours after delivery. In very severe cases 135 gr. chlor. hydr. and ¾ gr. morph. hyd. are introduced in the course of 14 hours (the administration of narcotics is *much more frequent than* is shown in the scheme, until the fits cease) ÷ chloroform narcosis several times. The forerunners of a fit are: increase of headache (which is recognisable in unconscious patients by the expression of the face, restlessness in bed), convulsive contractions, dimming of vision, and especially *increase of* blood pressure.

I may express my confidence that all the light cases of eclampsia will recover if the method is applied in the proper manner; the severe cases also should not prove fatal provided they do not contract pneumonia or sepsis. If this experiment resulted in the saving of even a few lives I would consider myself perfectly satisfied. It will, however, be of still greater benefit in the future.

In conclusion, I would like to express my deep gratitude to the Society for its willingness to render assistance in the elucidation of a problem which has hitherto produced so few results, in spite of the work of numerous scientists during two centuries.

ANÆSTHESIA FOR SHORT OPERATIONS ON CHILDREN.

BY O. STUART THOMPSON, L.R.C.P. LOND.,
CLIN. ASSIST., OUT-PATIENTS, AND LATE ASSISTANT CASUALTY OFFICER, HOSPITAL FOR SICK CHILDREN, GT. ORMOND-ST., LONDON.

THE choice of an anæsthetic must always rest with the anæsthetist who takes the responsibility of administering it, and in the case of an adult a skilled administrator will employ any of the usual anæsthetics with equal safety and without injurious effects to the patient afterwards. With children the matter is rather different.

When working in the out-patient department of the Hospital for Sick Children, Great Ormond-street, I particularly noticed two post-operative or, as I am inclined to believe, post-anæsthetic conditions: (1) An undesirable amount of collapse immediately following

ON AN IMPROVED PROPHYLACTIC METHOD OF TREATMENT OF ECLAMPSIA.[1]

BY PROF. B. B. STROGANOFF,
LENINGRAD.

AT the Battle of Trafalgar the British navy lost 1690 men, killed and wounded, whereas, according to Thomas Watts Eden, during the period of ten years from 1910 to 1920 there died through eclampsia in Great Britain and Ireland on the average 630 mothers per annum (22·5 per cent. of the cases) and double this number of children (47·8 per cent.). In other words, the loss of human lives during this period from eclampsia was higher than in that great battle.

It appears that in America the mortality from eclampsia is still greater. Leighton states that the death-rate in nine of the chief gynæcological institutions for five years reached 38·4 per cent. Rickets states that in U.S.A. 4000 mothers die annually of eclampsia, whilst, according to Coles Stricker, the average number of cases in that country amounts to 7500 per annum. If these figures are correct, the mortality reaches the enormous figure of 53·5 per cent. Hammerschlag also points out that the mortality from eclampsia in the United States is higher than in Europe. Whereas, in Paris, Berlin, Budapest, and Milan the mortality from eclampsia was about 1 to each 1000 deaths amongst women, in Chicago the proportion was 1·9, in San Francisco 2·9, and in New Orleans even 6·4 among the whites and 3·4 among the coloured population. There is reason to believe that the application of the improved prophylactic method of treatment of this disease will diminish the mortality by at least half.

History of the Method.

I first applied the method detailed later in 1897 and had no deaths from eclampsia in the first 57 cases. At the International Congresses in Paris (1900) and in Rome (1902) I reported 92 and 126 cases of eclampsia respectively with a mortality of 5 to 6 per cent. In 1907 I visited Rosthorn's clinic in Heidelberg and successfully treated a case who had had 11 fits in the course of 9½ hours and coma, with a pulse-rate of 150. Excellent results were obtained by me in 1909 in the clinics of Profs. Schauta and Piscacek (in Vienna), and in 1911 in the clinics of Profs. Bumm and Franz (Berlin). In 1908 I was able to report on 360 cases of eclampsia with a maternal mortality of 6·6 per cent. and a child mortality of 21·6 per cent. (the latter being eclampsias sub partu). Prof. Leopold, in Dresden, first applied my method in 1909, and obtained excellent results on 50 patients, out of which only four with complications died; 34 per cent. had no fits from the moment when treatment began, whilst 50 per cent. had only one to three fits.

The second to adopt my method in Germany was Prof. Krönig in Freiburg, whose five cases of eclampsia were completely satisfactory both as regards the mothers and the children. Since then this method spread further in Germany, in Switzerland (Herff), in Holland (Mingelen), in Sweden (Forssner), and even in the far Argentine (Enricque Zarate).

In 1918 I was able to collect from the literature—which is far from complete—2208 cases of eclampsia treated by this method and its variations, with a total maternal mortality of 9·8 per cent. Amongst 878 children born from eclamptic mothers, whose history is recorded, the mortality after treatment by this method was about 12 per cent. lower than in cases treated by other methods in the same clinics. Acting on behalf of Prof. Hinselmann, Dr. Weinsenfels discovered 1094 more cases up to 1924, which raises the number of cases to *3302, of which 357—i.e., 10·8 per cent.—terminated fatally.*

Still better results were obtained by us during the last 10–12 years after the method was somewhat modified. Out of 253 cases of eclampsia with fits at the State Clinical Institute of Obstetrics and Gynæcology (during 9½ years), and the Krassovsky Lying-in Hospital (from 1910 to 1921, when it was closed) only six deaths—i.e., 2·4 per cent.—were observed. In three of these cases we were dealing with hopeless patients. In one case we were unable to apply the prophylactic treatment in the absence of chloral hydrate, and in two cases of relatively light eclampsia death resulted from pneumonia and septicæmia. Thus, we had not a single death from eclampsia in cases that had not been neglected, and obtained figures regarding which Dr. Fürst[2] justly remarks: "In the statistics of the whole literature these favourable results stand out unsurpassed."

The Secondary Effects of the Treatment.

The beneficent effect of this treatment is confirmed by a series of other facts.

Thus, (1) *the number of fits diminished markedly.* In the course of the last ten years we obtained immediate cessation of the fits after the treatment was commenced in 40 per cent. of cases. In 45 per cent. the fits were repeated from one to three times, and only in 15 per cent. they were more numerous.

(2) *There is a large number of "intercurrent" eclampsias—i.e., cases in which there is freedom from fits for 12 hours and more before delivery.* Formerly, there were from 21 to 27 per cent. of such cases in prophylactic treatment. In the last group treated they amounted to 40·9 per cent. These figures do not, however, sufficiently characterise the power of the method in checking the fits, since many eclamptic patients are delivered in less than 12 hours after cessation of the fits. The efficacy of the method is more distinctly exhibited in cases of eclampsia sub graviditate; since 1916 66 per cent. of such eclampsias manifested an intercurrent course. This is a great advantage, since the pregnancy progresses after cessation of the fits and the child is delivered mature.

(3) *Psychical disturbances* are few in number and of a mild character. Out of 253 cases of eclampsia there were only four—i.e., 1·6 per cent. In one case the patient had five fits and after delivery suffered from nephritis, when mild symptoms of psychosis were observed for some days. In another patient, who had only one fit sub graviditate in the post-partum period, symptoms of icterus gravis were observed, in connexion with which psychosis was observed for several days. Recovery followed.

(4) *The mortality of children is relatively favourable.* For the whole group it amounts to 14·3 per cent., for eclampsia sub partu et sub graviditate 20 *per cent.*, and for post-partum cases 6·2 *per cent.* The most interesting group for us are the eclampsias ante partum and intra-partum, since in these the action of the drugs upon the fœtus is manifested. The mortality in this group was 20·1 per cent., but if the premature children (weighing less than 2000 g.), which died before treatment was commenced, from cold, operation, &c., are excluded, there remain only 6 per cent. attributable to eclampsia and treatment. And since 6·2 per cent. of fœtuses also perished in post-partum eclampsias, very little remains to the share of drugs.

(5) For the whole group of 253 eclampsias there was not a single death of the mother due to treatment. As is known, in the method of treatment of eclampsia by forced delivery some mothers die as the result of operation. In Bumm and Franz's cases about 4 per cent. of women died in consequence of operation.

(6) Diminution in the number of operative deliveries. These amounted to 56 per cent.

(7) Few cases of pneumonia.—4 in 253 patients.

(8) Rapid recovery of the patients.

On the basis of these 253 eclampsias, as well as of the analysis of the preceding 570 cases treated by the less perfect variety of the prophylactic method, I have arrived at the conclusion that a favourable prognosis can be given for the mother in cases of eclampsia that have not been neglected.

---

[1] Being a paper read at the Section of Obstetrics and Gynæcology of the Royal Society of Medicine on July 3rd, 1924.

[2] Zentralbl. f. gynäk., 1924, No. 16, 843.

An extremely interesting confirmation of this is presented by the immense monograph on eclampsia by Prof. Hinselmann, of Bonn, in collaboration with 12 other specialists. He praises highly the great efficiency of this method, and points out that if my figures are achieved by others using my method the problem of the treatment of eclampsia may be regarded as solved. One may hope that the British and American cases of eclampsia are not more intractable than the Russian and German ones.

Proposals for trial in England.

I would like to verify the method in this country and possibly improve the details; at the same time it is my desire to collect the 47 cases to make up a total of 300 treated by this method.

1. The first condition necessary for a trial of my method would be to give me the opportunity of taking part in the treatment of as many cases of eclampsia occurring during the next $1\frac{1}{2}$–2 months of my sojourn in London, as possible. The authorities could perhaps select four or five lying-in institutions in London and request their directors to provide me with the necessary material. It is important to provide for this purpose a separate hygienic room.

2. The exact application of the method is only possible with the help of an experienced qualified assistant who has a knowledge of the method. It is also necessary to have a midwife capable of looking after the eclamptic patient according to the requirements of the method. If a nurse is available, she also should be instructed accordingly. If it were possible to choose these persons beforehand, I would speak to them and instruct them in the technical part of the process. Of course, it is important to have the necessary medicaments and instruments always ready (morphine, chloral, chloroform, oxygen, digitalis, instruments for venesection and for delivery).

3. I consider the demand of T. W. Eden that eclampsias should be classified as mild, severe, and moribund to be very important. To the seven features by which he characterises the severe cases I would add the following two—nephritis of long duration and fits recurring four or more times during two hours. It would seem to me desirable to establish another category of severe cases; those manifesting two-thirds of the symptoms of severity should be referred to as morituræ, or very severe cases, with an additional symptom—*presence of cerebral hæmorrhage.*

4. Considering the importance of this experiment not only in England but in all civilised countries, it would be desirable to establish a special committee for the exact estimation and observation of the cases. Such a committee would naturally be composed of the directors of the lying-in departments of the coöperating institutions, presided over by a person selected by the Section of Obstetrics and Gynæcology of the Royal Society of Medicine.

I am prepared to present myself to take part in the treatment of cases by day and by night.

The Scheme of the Method.

The following is the brief scheme of the method of treatment which is more fully described elsewhere.[3]

Eclamptic patients in most cases die from the destructive action of the fits upon the heart, respiratory centre, &c. Therefore the fits must be repressed. Eclampsias sub graviditate and eclampsias sub partu are treated with equal energy. Post-partum eclampsias have a milder course, and therefore in most cases require the administration of smaller doses of narcotics. Sometimes they are extremely severe and then require maximum doses. During the fits the patient should be protected against injuries, the tongue protected against bites, and oxygen should be given after fits to remove asphyxia. Chloroform is harmful in typical fits, but if the patient is breathing (clonic convulsions) it is useful.

1. *Removal of all irritations:* (*a*) All noise to be eliminated, (*b*) room darkened, (*c*) examinations reduced to a minimum, (*d*) if possible, separate room and constant observation. Transfer to room under chloroform.

2. *Administration of narcotics:* Morphine and chloral hydrate according to scheme below.

The beginning of treatment: $\frac{1}{4}$ gr. ($\frac{1}{6}$–$\frac{1}{3}$ gr.) morph. hyd. hypodermically. 1 hour: 30 gr. (38–22 gr.) chlor. hydr. per os or per rectum. 3 hours from the beginning of the treatment: from $\frac{1}{4}$ gr. ($\frac{1}{6}$–$\frac{1}{3}$ gr.) morph. hyd. hypodermically. 7 hours: As at 1 hour. 13 hours: 22 gr. (15–30 gr.) chlor. hydr. 21 hours: 22 gr. (15–30 gr.) chlor. hydr. Dose increased in severe eclampsia in the case of strong individuals, and diminished in mild forms. When patient is conscious chloral hydrate is introduced per os, and in unconscious condition per rectum with milk and physiological salt solution. During the first two intervals we frequently administer chloroform 10–20 minims in the presence of prodromata of a fit. On the second day undelivered patients receive 15–22 gr. chlor. hydr. t.i.d. In the absence of fits during 14 hours and when the patient is in good condition the dosage may be diminished.

3. If the fit recurs two to three times, or even once in severe form, in spite of administration of morphine and chloral hydrate, it is necessary to perform venesection, drawing off 400 c.cm. of blood. This is not resorted to if delivery is expected within the next 1–2 hours.

4. As soon as the eclamptic patient can be delivered without harm to herself and child, delivery is undertaken, either with forceps, by extraction, or rarely, by version. In the absence of contra-indications we rupture the bag of membranes, if the os has dilated to two fingers in a multipara, and about three fingers in a primipara.

5. *Maintenance of regular functions of chief organs:*—

(*a*) Kidneys and skin: Patient kept warm with hot water bottles at the feet and in the region of the kidneys; hot tea diluted with milk should be given; unconscious patients must have milk and physiological salt solution āā (about 1000 c.c. per diem), usually with chloral hydrate, per rectum.

(*b*) Lungs: Oxygen after a fit, pure warm air, removal of all hindrances to respiratory movements; unconscious eclamptic patients should be kept chiefly on the right side; careful cleansing of the mouth and nose from mucus, blood, and vomited matter.

(*c*) Heart: Administration of fluids (see (*a*)), when weakened after numerous fits—digitalis (if the pulse-rate is 110 or higher)—and when the heart is still weaker—camphor, caffein. Patients admitted from outside after six or more fits immediately undergo narcotic treatment and venesection. Continuous observation of patient and child during the first 24 hours after delivery. In very severe cases 135 gr. chlor. hydr. and $\frac{3}{5}$ gr. morph. hyd. are introduced in the course of 14 hours (the administration of narcotics is much more frequent than is shown in the scheme, until the fits cease) + chloroform narcosis several times. The forerunners of a fit are: increase of headache (which is recognisable in unconscious patients by the expression of the face, restlessness in bed), convulsive contractions, dimming of vision, and especially increase of blood pressure.

I may express my confidence that all the light cases of eclampsia will recover if the method is applied in the proper manner; the severe cases also should not prove fatal provided they do not contract pneumonia or sepsis. If this experiment resulted in the saving of even a few lives I would consider myself perfectly satisfied. It will, however, be of still greater benefit in the future.

In conclusion, I would like to express my deep gratitude to the Society for its willingness to render assistance in the elucidation of a problem which has hitherto produced so few results, in spite of the work of numerous scientists during two centuries.

ANÆSTHESIA FOR SHORT OPERATIONS ON CHILDREN.

BY O. STUART THOMPSON, L.R.C.P. LOND.,
CLIN. ASSIST., OUT-PATIENTS, AND LATE ASSISTANT CASUALTY OFFICER, HOSPITAL FOR SICK CHILDREN, GT. ORMOND-ST., LONDON.

THE choice of an anæsthetic must always rest with the anæsthetist who takes the responsibility of administering it, and in the case of an adult a skilled administrator will employ any of the usual anæsthetics with equal safety and without injurious effects to the patient afterwards. With children the matter is rather different.

When working in the out-patient department of the Hospital for Sick Children, Great Ormond-street, I particularly noticed two post-operative or, as I am inclined to believe, post-anæsthetic conditions: (1) An undesirable amount of collapse immediately following such minor operations as dissection of tonsils, &c.; (2) a fear of the doctor afterwards.

From the anæsthetist's point of view, children may be divided into two classes: (*a*) Those who take the anæsthetic quietly, and (*b*) those who will not take it unless it is forced on them. The first class includes those children who are very ill, and, though it used to be taught that "children take gas badly," it will be found by experience that they take gas and oxygen well. It is now given almost as a routine at the Hospital for Sick Children in cases of hypertrophic pyloric stenosis, and the results of operation in these cases are encouragingly successful. It is a form of anæsthesia that might be more frequently employed for children.

It is the second class of child that I particularly wish to consider. The anæsthetist who also does private practice will have the opportunity to study the after-effects of anæsthesia on children, and if he has to treat the children afterwards, he must soon realise the harm caused by the administration of an anæsthetic through shock and the subsequent fear of the doctor; this is sometimes so great that it is almost impossible to do anything with the child for a year or more.

To avoid these two after-results, I consider the most important thing to do is to shorten the period of induction. The drug that produces anæsthesia most rapidly is ethyl chloride, and this, followed up with ether, I believe to be the best form of anæsthetic for these children at present. It was said to me by a well-known anæsthetist that a drug that produces anæsthesia so rapidly must *ipso facto* be a dangerous drug to use. In the hands of an indifferent administrator this is doubtless true; but experience teaches us everything, and in a series of 10,000 administrations of ethyl chloride given in our dental department no bad effects were noticed. On the strength of this, I used ethyl chloride followed by open ether in a series of 200 cases in the out-patient theatre without observing any ill-effects or alarming symptoms or having any difficulty in the administration.

I give ethyl chloride on an open mask, the amount used being about 3 c.cm. for a child of 5 years old. It is sprayed on the mask, which is immediately applied over the face and is followed by open ether later on. The child is instructed to blow it away, and four "blows" with the inspirations that accompany them are usually sufficient to produce loss of consciousness. The child seldom struggles, and even if it does there is no prolonged induction period—the time being only a few seconds—and consequently there is little recollection afterwards of the struggle with the anæsthetist, and less fear of "the doctor," so that one can still do something with the child again.

It is quite possible to get a child under the anæsthetic rapidly with open ether, but it means "pushing" the anæsthetic, and anyone who has had the experience of breathing with a large amount of ether on the mask knows how extremely unpleasant it is. I can vouch for this from personal experience. With the avoidance of a prolonged induction period, I have noticed less shock following short operations. This shock, in the case of such short operations as are done in an out-patient theatre, I am therefore inclined to regard as post-anæsthetic rather than as post-operative.

The question of administration of an anæsthetic to a child is not complete without reference to the handling of the child and the obtaining of the child's confidence. This is just as important for the anæsthetist as for the physician. Children should never be forced to lie down suddenly, it nearly always frightens them, and if the mask is clapped over the face and ether forced on to them, it is long before they recover their confidence in a doctor. If the anæsthetist had to treat these frightened children he would realise the importance of the careful handling of a child.

As regards chloroform, I do not intend to enter into any discussion as to its comparative merits, or to resuscitate the tedious ether-versus-chloroform controversy. I give children chloroform when necessary, and will admit that it produces a gentle anæsthesia, but I have never liked it for children.

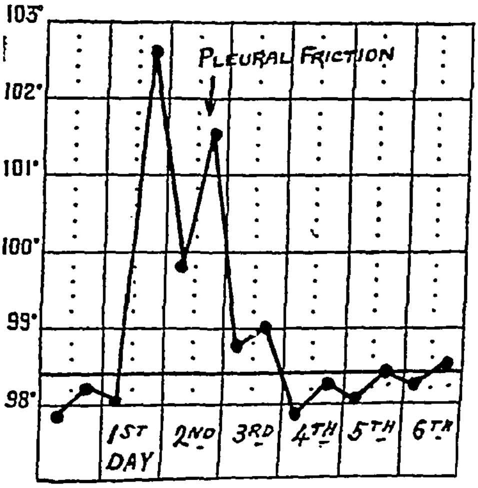
Clinical and Laboratory Notes.

EPIDEMIC PLEURISY.

By Bruce Williamson, M.B., Ch.B. Edin.,
HOUSE PHYSICIAN, PADDINGTON GREEN CHILDREN'S HOSPITAL.

The following is a brief account of a small epidemic of pyrexia, associated with dry pleurisy, which occurred during the month of June in the country branch of the Paddington Green Children's Hospital. It can only be described as an acute onset of pyrexia, lasting three or four days, associated with the development of a dry pleurisy which becomes evident usually on the second day of the fever. The ætiology is unknown. In all, 13 cases have come to my notice, of these three were among the nursing staff and the remainder children of varying ages, from 4 months to 8 years.

The incubation period appears to be short, probably under a week. It was noticeable during the outbreak that fresh cases occurred usually in groups of three, at three to five day intervals, and all have been so remarkably alike in onset, symptoms, and progress that there is little room to doubt that the illness is a definite clinical entity. The onset in all cases was abrupt and ushered in by a feeling of chilliness, a complaint of mild headache associated with a feeling of being out of sorts, and general aches all over the body, less severe than those associated with influenza. Such were the symptoms described by the adult patients, and probably also present in the younger cases. Within an hour or two the temperature began to rise and soon reached 102° F., and the pulse-rate increased to 120 or more, the younger patients being 20 to 40 beats higher. The respiratory-rate increased, and the whole picture closely resembled the onset of pneumonia. During the next 24 hours the pyrexia was maintained and might even touch 104°. Amongst the younger patients two had moderate diarrhœa. Examination on the first day revealed no signs of any inflammatory process in the lungs or elsewhere. On the second day the temperature fell slightly, but a secondary rise occurred the next day. It was on the second day, as a rule, that the patient complained of a catching pain on breathing, and the characteristic pleural friction of a dry pleurisy was heard. The area over which it was heard was generally confined to a very circumscribed single area at one base, more often in the axillary line. By the fourth day the fever had subsided and the pulse and temperature were again normal, the pleural friction and its associated pain remaining for a day or two longer and constituting the sole sign and symptom. A week after the onset the pleural rub had disappeared and none of the cases in this series has been complicated by fluid, nor has there been evidence of lung



implication at any time. In two cases a marked sudaminal rash, generalised over the body, followed the fall of temperature.

With regard to this series daily examination has not been always available, and in only seven out of the 13 cases was the presence of pleural friction established, these seven being all children. But there is little doubt as to its presence in the three adult cases, members of the nursing staff, who described the typical pain associated with the inspiratory effort, and they were aware that they had pleurisy. All the children complained of pain in the side, with the exception of the infant of 4 months, in whom it may have been present as she was extremely fretful and cried continuously for a day. The temperature chart and pulse were similar, and the duration practically identical in all cases.

RUPTURE OF THE RECTUS ABDOMINIS PRODUCED BY VOMITING.

BY JOHN WHITTINGDALE, M.B. CAMB., F.R.C.S. ENG.

SPONTANEOUS rupture of the rectus abdominis muscles may occur as the result of great and prolonged contraction during labour, or of violent convulsive spasms produced by the action of strychnine and of tetanus toxin upon the spinal cord. The case here reported presents the following features of interest: (1) Predisposing causes—advanced age and debilitated condition of the patient, (2) exciting cause—violent vomiting, (3) difficulty of diagnosis and unexpectedness of the condition found at operation.

The patient, a charwoman, aged 74 years, had been confined to her house suffering from gradually progressive myocardial failure.

History.—She had had 12 children and was able to do house-work until the age of 73. When first seen on Sept. 10th, 1923, she complained of difficulty in breathing, cough, and swelling of the legs, with cyanosis of lips, pulsating veins in the neck, irregular radial pulse, and moist sounds audible over both lungs. The abdominal wall was flaccid and the colon visibly distended and tympanitic. There was tenderness over the hepatic area of the abdomen. The urine was scanty and contained albumin. Ten minim doses of tincture of digitalis with 5 gr. of ammon. carb. were given four-hourly. Sept. 12th: Complained of diarrhœa. Digitalis replaced by 5 minim doses of tinct. strophanthi. 16th: Vomited three times, with cramp-like pains over abdomen. Strophanthus stopped and hot flannels applied. 18th, 8 P.M.: Vomited all day. Sudden violent pain in right iliac region with a sensation as if something had given way. Complete constipation with retention of urine. Abdomen distended and tympanitic and muscles over right iliac region tender and rigid.

The patient was now very collapsed and apparently moribund. A diagnosis of mesenteric embolism was suggested and operation was not advised, as the patient did not seem likely to survive the journey to hospital. A hypodermic injection of morphine and atropine was given. Sept. 19th: Patient much better, retained water, tea, and jelly; complained of lump in right side of abdomen. On examination, a large swelling was found occupying the right half of the abdomen, extending from the symphysis pubis to the right hypochondrium; the overlying skin showed ecchymosis. The mass was pyriform in shape with well-defined borders; of solid consistence and tender to touch. Patient was removed by car to the Yeatman Hospital, Sherborne, a journey of eight miles.

Operation (20th).—Under chloroform a right paramedian incision was made extending from the symphysis pubis to the umbilicus. The superficial fascia was œdematous. On opening the anterior layer of the sheath of the rectus blood-clot escaped and a large ragged cavity was found in the substance of the muscle from which 6 oz. of blood and clot were evacuated. This was treated with spirit and bipp. It was then obliterated as far as possible with interrupted catgut sutures. The anterior layer of the sheath and the skin incision were closed without drainage. The wound healed per primam and the patient returned home on Oct. 8th.

On discharge, the patient was comfortable and showed no sign of myocardial embarrassment as long as she remained in her chair. The œdema of the feet and legs had disappeared and the breath sounds were clear.

It is worthy of note that in spite of the advanced age of the patient and the considerable degree of shock to which she was subjected, the ultimate result was an amelioration of her general condition.

THE GROWTH OF MAMMALIAN TISSUES IN PURE SERUM.

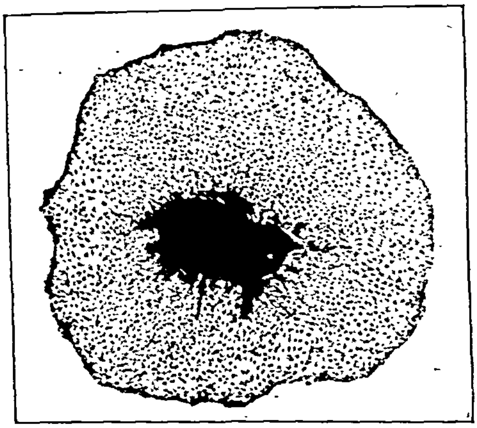
BY THOMAS LUMSDEN, M.D. ABERD.

(*From the Department of Experimental Pathology, Lister Institute.*)

Carrel and Ebeling[1] have succeeded in growing chicken fibroblasts in vitro for over 12 years, but no medium has yet been discovered in which mammalian tissues or a pure strain of glandular epithelium can be grown indefinitely. Mammalian tissues do, however, grow vigorously for some weeks in vitro, but the media employed have been very complex and the methods troublesome. Dr. A. H. Drew, who kindly showed me his technique, uses a mixture of (1) modified Locke's fluid, (2) embryo extract, (3) serum, and (4) autolysed tissue extract. He tells me that the shortest time in which anyone has yet become proficient in this technique is four months.

The purpose of this note is to indicate that equally if not more vigorous growth (Fig. 1) may be obtained in pure serum alone, providing that certain essential precautions are taken. The first of these is that the serum must be absolutely sterile, and the second, scarcely less important, is that its pH must not exceed 7·7.

FIG. 1.



Young rat kidney (× 30). Three days' growth in pure rat serum.

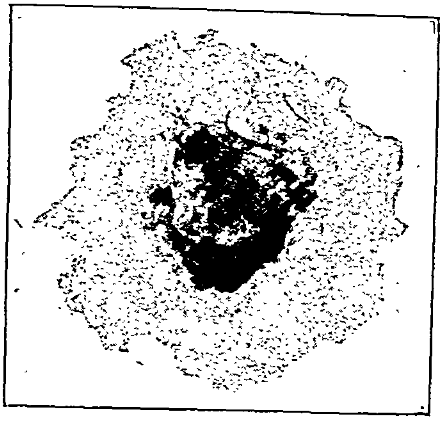
It is, I suppose, common knowledge that if serum is freely exposed to the air it rapidly gives off CO_2, so that if when first exposed its pH was 7·5, in five or ten minutes the pH will be 8 or over. This being so, it is essential either to prevent this loss of CO_2 or to replace it by exposing the serum to an atmosphere of 5 per cent. CO_2 in air for 10 to 15 minutes. There are some other variable factors in the serum and in the tissue which I am attempting to ascertain, but if the serum is sterile and of optimal reaction (pH 7·5 or so) then from 80 to 100 per cent. of successes may be anticipated. The use of pure serum obviates the need for embryo and autolysed tissue extracts, and for the use of filters, ice, &c. The simplification in the technique is so great that anyone trained to asepsis can obtain vigorous growth after a week's practice.

Technique.—The blood is drawn from the heart of a half-grown animal as quickly as possible, and is at once poured into a centrifuge tube, which is tightly corked. After separation of the clot and centrifuging, the serum is transferred rapidly, and with rigid aseptic precautions, to a series of capillary tubules made of resistant glass; these are immediately sealed up. The pH of the serum now remains practically constant and should be 7·5 or 7·6. It can be used as a culture-medium for several weeks at least. Heterologous serum appears to act almost as well as homologous. (Fig. 3.) The tissue used was almost invariably the kidney of a rat three to four days old, but heart, spleen, testis, cartilage, &c., also grow in serum alone. There is no magical dividing line between born and unborn animals in regard to growth, but the younger *the tissue the earlier it begins to grow. Both* embryo and autolysed tissue extracts have a buffering effect on serum; up to now I have seen no evidence that they have (on mammalian tissues) any other action. I have not found that re-feeding growing cells with autolysed tissue extract had any harmful effect. (Fig. 2.) All growing tissues require to be re-fed with fresh serum daily or at least every second day.

---

[1] Jour. Exp. Med., 1913, 1919, 1922.

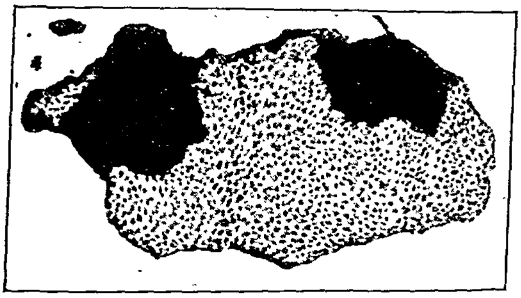
Fig. 2.



Embryo rat kidney (× 15). Six days' growth in serum and autolysed tissue extract (equal parts).

Growth takes place either in the form of a carpet of cells adhering to the cover-glass or in spheroidal form if adhesion has not occurred; often these two varieties of growth coexist. The newly forming cells appear to feed on the serum constituents, for I have been able to remove the old fragment completely; the carpet of new cells left behind generally shrivels, but from the shrivelled mass a new carpet of freshly-growing cells may develop.

Fig. 3.



Young rat kidney (× 37½). Grown in rabbit serum for five days, showing junction of two carpets originally separate.

Cells only grow actively if anchored in some way —e.g., to the cover-glass, to a foreign body (cotton fibre or such like), or the original fragment may be the point d'appui.

If injured mechanically or if fed with an unsatisfactory medium, the growth may become partially detached from the coverslip and shrivel rapidly, assuming a lace-like or sometimes a tubular appearance. Even if the medium is apparently satisfactory, new cells tend to shrink and become fatty after four or five days; the first carpet may disintegrate, but a new one soon replaces it, and so growth continues for three or four weeks with a "wave-length" of a few days.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this Society held on June 4th, Prof. B. P. Watson, the President, being in the chair, Dr. Francis J. Browne read a communication on

Further Observations on the Prevention of Antenatal, Intranatal, and Neonatal Death.

Dr. Browne explained that his paper was based on 200 consecutive cases of stillbirth occurring in fœtuses of viable age. The method of investigation was the same in each case—a complete post-mortem examination of the fœtus or infant and placenta was made, including a microscopical investigation of the organs, and the case-history was obtained. The mother was then examined and questioned regarding her family and personal history, and when possible the father was also questioned. From the information thus obtained an attempt was made to arrive at a decision as to the cause of death and to draw conclusions of practical importance regarding the management of pregnancy and labour. In a previous paper read to the Society, Dr. Browne had classified the causes of death under ten headings, such as craniotomy, asphyxia, or syphilis, &c., but in this series of cases he had adopted a new classification which possessed certain advantages over his former one. He divided the causes of death into three sections: antenatal, intranatal, and neonatal, and these were further subdivided into several groups.

Antenatal Death.

The causes of antenatal death had been classified as follows: 1. Toxæmic: (*a*) syphilis, (*b*) placental infarction, (*c*) utero-placental apoplexy, (*d*) premature senility of the placenta, (*e*) maternal glycosuria, (*f*) eclamptic convulsions, (*g*) drugs. 2. Mechanical: (*a*) placental separation in placenta prævia, (*b*) placental separation from trauma, (*c*) knots or torsion of the cord. 3. Developmental: (*a*) one artery in the cord (?), (*b*) small placental area, (*c*) general œdema of the fœtus, (*d*) other congenital abnormalities. 4. Undetermined: Syphilis was found to be the most frequent cause of antenatal death occurring in 24 cases, but in only 15 of these was the spirochæte demonstrated. In attempting to diagnose the cause of death in the macerated fœtus little in the external appearances was of help except that the abdomen might be prominent in the syphilitic fœtus on account of the large liver. Internally, the liver in the syphilitic fœtus was found to be of firm consistence owing to the presence of a dense framework when cirrhosis was present, and often of a greyish-brown colour, and the organ enlarged. In the non-syphilitic liver there was little fibrous tissue; the organ was extremely cellular, its glycogen content was large, and maceration resulted in a rapid diminution of its size. A normal fresh liver might weigh as much as one-twelfth of the body-weight; anything over this was probably syphilitic, and the spleen of a normal fresh fœtus might weigh one one-fiftieth of the body-weight. Any weight ratio over 150 was probably an evidence of syphilis. Dr. Browne had found that in the case of a fresh fœtus at the eighth month or over the weight ratio of the placenta might vary normally between 4 and 16, but that a ratio above 4 was abnormal provided there was no abnormal intra-placental clotting (red or white infarcts). Below the eighth month this rule did not hold and a ratio of two or even one or less might be looked upon as normal. Dr. Browne had never seen red infarcts in a syphilitic placenta, and this was of interest because whatever the explanation of infarct formation, the syphilitic placenta above all others was the one in which obliterating endarteritis of the fœtal vessels was found. In albuminuria of pregnancy or chronic nephritis, red and white infarcts were extremely common. In the speaker's experience the presence of a strongly positive Wassermann reaction was very decisive evidence of the presence of syphilis in a pregnant woman. There was no doubt also that a woman might have a persistently negative Wassermann reaction and yet produce a succession of syphilitic fœtuses, but Dr. Browne had never met with a case in which a mother with a negative Wassermann produced a spirochæte positive fœtus. This, of course, raised the question as to how far it is justifiable to diagnose syphilis of the fœtus from the so-called secondary signs—viz., enlarged liver, spleen, and placenta. In doubtful cases there was also always the therapeutic test, and full courses of N.A.B. might be given to the mother. Maternal glycosuria was a rare cause of fœtal death. At present the prevention of antenatal death was practically limited to cases of albuminuria and syphilis, and in Dr. Browne's opinion about 60 per cent. of his cases might have been prevented by adequate antenatal supervision.

Intranatal Death.

Dr. Browne classified the causes as follows: Traumatic: (*a*) craniotomy, (*b*) cerebral hæmorrhage, (*c*) asphyxia, (*d*) suprarenal hæmorrhage, (*e*) other injuries. 2. Infective: pneumonia. 3. Toxæmic: scopolo-morphine narcosis. 4. Developmental. 5. Undetermined. Amongst these cases asphyxia accounted for more than half the total. Craniotomy was performed in 14 cases of the 200. In five of the 14 cases there was catarrhal pneumonia present.

Considering cerebral hæmorrhage, Dr. Browne pointed out that it was entirely a matter of the site and degree of hæmorrhage whether death took place during or shortly after birth. Referring to the hæmorrhagic diathesis, attention to which had been drawn by Warwick, the speaker said that, though he had seen no case in which it was necessary to assume the presence of this diathesis in his first series of cases, since then he had come across two cases which might be placed in this category. Breech delivery was ten times more likely to give rise to cerebral hæmorrhage as is delivery by the vertex. Dr. Browne then described in detail the ætiology of cerebral hæmorrhage in his cases. It was probable that undue haste in delivery of the after-coming head was responsible for many of the injuries. The unborn child could apparently bear the cutting off of its oxygen-supply for a much longer period than an adult and might be left undelivered after birth of the breech for as long as 20 minutes without injury. Potter, out of his great experience of breech deliveries, had said that instead of using forceful haste we must be deliberate and deliver gently and gradually the after-coming head. The points to be observed in the prevention of cerebral hæmorrhage were: (*a*) avoidance of breech deliveries by the performance of external cephalic version about the commencement of the ninth month; (*b*) the avoidance as far as possible of difficult forceps deliveries, and also hasty delivery; and (c) the limitation of induction of labour to cases which have completed the thirty-fifth week. A study of 36 cases of intrapartum asphyxia revealed the fact that about 75 per cent. might reasonably be classed as preventable. There was no doubt that many cases of asphyxia which occurred during prolonged labour, natural or otherwise, could be prevented by the induction of labour about ten days before term.

The value of the hydrostatic test for live birth was then discussed, and certain fallacies, such as artificial respiration, pointed out. But apart from these it was evident the lungs were not infrequently more or less inflated in infants that had unquestionably been born dead, and in whom no method of artificial respiration had been carried out. Dr. Browne expressed his entire agreement with the statement in Taylor's "Medical Jurisprudence" that "for respiration however complete or incomplete to be considered proof of live birth, an eye-witness to these respirations is essential." In his two series of cases there were 27 cases in which suprarenal hæmorrhage was the cause of death and in this connexion, he said, three facts stood out—viz., its frequent association with asphyxia, its greater liability to occur in the right gland, and its greater frequency during breech delivery. Suprarenal hæmorrhage was probably caused by the backward pressure of blood in the inferior vena cava found in asphyxia and by the compression of the latter between the liver and vertebral column in breech delivery.

Neonatal Death.

Of this there were in his present series 73 cases, and the many causes were classified under traumatic, infective, prematurity, toxæmic, developmental, and other conditions not peculiar to the new-born—e.g., gastro-enteritis. By far the commonest cause was an antenatal infection—e.g., syphilis. Pneumonia was found in 24 out of the 73 cases. It was probable that the infection might occur and the disease commence before birth. Even in those cases in which the disease was found to be advanced at autopsy, the true condition had not been suspected during life and no characteristic symptom noted which might have led to a physical examination. When a young infant was cyanosed, with cold skin and extremities, fed badly, and was fretful, pneumonia should be suspected. Dr. Browne went on to describe some cases of intranatal pneumonia and discussed the path of infection, and he suggested that when a fœtus was being asphxiated its respiratory centre was stimulated by the accumulating CO_2 in its blood and thereby the fœtus inspired, drawing infective mucus or liquor into the trachea or bronchi. The author then briefly referred to toxæmic causes and prematurity. Regarding the prevention of stillbirth, Dr. Browne said that it was surely unnecessary to emphasise the need for adequate antenatal supervision during pregnancy, but there were one or two points to which he would like to draw particular attention. He thought that a strong case could be made out for the routine induction of labour in primigravidæ about ten days before term. This guarded against the production of asphyxia and an easier and less prolonged labour was thereby ensured. Secondly, he would emphasise the danger of breech deliveries and urge the necessity for prophylactic external version at the beginning of the ninth month. Much could be done to shorten labour by external rotation of posterior cases by means of pads, and special wards set apart for infants would do much to guard them from such infections as pneumonia.

Prof. B. P. WATSON said that he admired the way in which Dr. Browne had tackled this subject.

Dr. WILLIAM FORDYCE doubted the wisdom of inducing labour ten days before full time, and Dr. HAIG FERGUSON also joined in the discussion.

Dr. BROWNE briefly replied.

Exhibition of Cases and Specimens.

Dr. HAIG FERGUSON described in detail a strange case of a pendulous tumour of the labium majus exhibiting unusual features. The case had been taken for a hernia into the labium, but laparotomy proved that it had no connexion with the peritoneal cavity, and he had dissected out the growth. Dr. Ferguson could find no record of an exactly similar case in the literature, and a pathologist had expressed the opinion that the growth was a telangiectatic fibromyoma with hyaline degeneration.

A number of specimens were then shown. Dr. FORDYCE described an unusual fibroid tumour.—Dr. FERGUSON showed a uterus with squamoid metaplasia of the gland epithelium with early malignancy, and in the same patient an ovary showing early sarcoma.—The PRESIDENT described three specimens: (*a*) an ovary with chocolate cysts; (*b*) large ovarian tumour removed from a patient six months pregnant; (c) uterus removed by vaginal hysterectomy from a case of complete prolapse showing great elongation of the supravaginal cervix.

Reviews and Notices of Books.

Human Protozoology.

By Robert W. Hegner, Ph.D., and William H. Taliaferro, Ph.D. New York: The Macmillan Company. 1924. Pp. 597. 21s.

As an introduction to the subject of medical protozoology this book satisfies a need. The information, which has been gathered from authoritative sources and the authors' own experiences, is presented in a clear and intelligible form. There are two coloured plates of malarial parasites and numerous illustrations in black and white, many of them original. The book assumes no previous knowledge of the subject, and will prove of great assistance to those who approach this branch of medical science for the first time. It represents essentially the subject-matter of the course in protozoology given by the writers in the School of Hygiene and Public Health of the Johns Hopkins University, and will be of considerable assistance to those who are taking out courses in tropical medicine at one or other of the recognised schools.

After a few introductory remarks on the organisation and method of reproduction of protozoa in general, the four classes—Sarcodina, Mastigophora, Sporozoa, and Infusoria—are considered in detail. In the description of each class a section devoted to general considerations, including the morphological characteristics, classification, and physiology of the class, with reference to free-living as well as parasitic forms, is followed by a detailed account of the parasites of man, with some reference to the allied species which occur in animals. The book concludes with two chapters in which the genetics and physiology of reproduction and the diagnosis of the intestinal protozoa are discussed. In the section dealing with the amœbæ parasitic in man the well-known species are carefully described; the generic title *Entamœba* is spelt *Endamœba*, a procedure which though usual in America is not generally adopted in other countries.

In considering the cultivation of the *Entamœba histolytica* Cutler's work is mentioned, and reference is made to Barret and Smith's successful cultivation of an *entamœba* of the turtle. The parasitic Mastigophora are dealt with in two chapters entitled Hæmoflagellates and Intestinal Flagellates. In the former are considered the trypanosomes and leishmania which infect man, as well as some of the forms which occur in animals. It would have been advantageous if room could have been found for a more detailed and illustrated description of *Trypanosoma vivax*, *Trypanosoma congolense*, and *Trypanosoma evansi*, especially as considerable space has been devoted to *Trypanosoma lewisi* of the rat. The intestinal flagellates of man are carefully described. It is assumed that the flagellate described as *Tricercomonas intestinalis* by Wenyon and O'Connor is the same as one previously named *Enteromonas hominis* by Fonseca; this is by no means clear, however, as the descriptions of the two organisms vary considerably. The Sporozoa receive due attention; the hæmogregarines are grouped in a single genus *Hæmogregarina* under the Hæmosporidia, a procedure not in accord with recent investigations. In the chapter devoted to the genetics and physiology of reproduction the various phenomena, such as binary fission, conjugation and its physiological effects on the race, endomixis, and asexual and sexual reproduction in its relation to inheritance and race production are explained with special reference to parasitic forms. The chapter on the diagnosis of intestinal protozoa presents valuable information. The method of making preparations of fæces for diagnostic purposes, concentration methods for encysted forms, the vegetable organisms which may cause confusion, and the large group of coprozoic organisms which often lead students astray, all receive consideration. Finally there is included a comprehensive bibliography as well as a good index of authors and subjects.

This useful volume can be thoroughly recommended.

Ear, Nose, and Throat.

Diseases of the Nose, Throat, and Ear. For Practitioners and Students. Edited by A. Logan Turner, M.D., F.R.C.S.Edin., Surgeon-Consultant, Ear and Throat Department, Royal Infirmary, Edinburgh. Bristol: John Wright and Sons. 1924. Pp. 413. 20s.

In 1912 Dr. W. G. Porter published a very useful manual of moderate size on diseases of the throat, nose, and ear for practitioners and students; this proved highly successful, and a second edition was brought out in 1916 edited by Dr. P. McBride for the author, who was at that time absent on war service. Dr. Porter was killed in action in France in 1917, and a third edition was published in 1919, under the editorship of Dr. A. Logan Turner, by his former colleagues in Edinburgh, as a tribute to his memory. This has now been expanded under the same editorship into the present volume. It is planned on lines similar to those of Dr. Porter's original book, and has been expanded by about 50 per cent.; being written for practitioners and students, full details of the larger operations are not given, but only sufficient to provide a clear idea of their method and scope; while the indications for such operations are fully discussed, the details of after-treatment, which often falls to the practitioner, might in places be more fully described. Dr. A. Logan Turner and Mr. W. T. Gardiner are responsible for the section on diseases of the nose, Dr. Logan Turner for that on the paranasal sinuses; Mr. Douglas Guthrie has undertaken the pharynx and nasopharynx, Mr. J. D. Lithgow the larynx, Mr. G. Ewart Martin peroral endoscopy, and Mr. J. S. Fraser the ear. The illustrations are many and good; the book is well balanced and clearly written, and may confidently be recommended for the use of students and practitioners.

Chirurgie de l'Oreille, du Nez, du Pharynx, et du Larynx. Second edition. By Georges Laurens. Paris: Masson et Cie. 1924. Pp. 1052. Fr. 100.

We congratulate Dr. Georges Laurens on the production of this standard work on the subject. The steps of operations are well described, alternative methods being given; the indications and contra-indications for particular operations are discussed, and after-treatment and results of operation are considered. The illustrations are numerous and show clearly the stage of operation under consideration. Besides the more common operations, those less often practised receive full consideration; thus removal of tumours of the cerebello-pontine angle is described, together with a brief account of their symptoms; and such subjects as stenosis of the larynx and trachea, and difficulty of decannulisation after tracheotomy, receive adequate attention, while endoscopy is well described and illustrated. In most subjects the practice is very similar to that of this country, the most marked difference being the much greater use of local and far less frequent employment of general anæsthesia; each operation is preceded by a complete and illustrated description of the technique of local anæsthetisation, which will be most useful to surgeons here who are less familiar with the method. Of laryngectomy the author says, "Two points are to be remembered: the superiority of local and the dangers of general anæsthesia"; although the technique of the former is difficult and elaborate, we might perhaps employ it with advantage more frequently in this country for major operations on the larynx and trachea, as we now do for such smaller operations as tracheotomy. But we disagree entirely with the recommendation for removal of tonsils in children, to operate without anæsthesia, or to give ethyl chloride with the child in the sitting posture; the nervous shock caused by these operations without anæsthesia far more than offsets the slight danger of a skilfully given general anæsthetic, and ether is preferable to ethyl chloride as it gives time for a deliberate operation and the control of hæmorrhage. Indeed, we cannot but consider that, in the whole matter of tonsil operations the practice in France, as shown in this and other recent publications, is behind that of Great Britain and America. Dr. Laurens prefers tonsillotomy, and the method of *morcellement*, to complete removal, although he admits that, "on assisting at a well-performed tonsillectomy, one is sometimes surprised to see a buried tonsil, quite small in appearance, show at the end of the forceps as a fungating tumour of a size which one would never have suspected and infiltrated with infected caseating foci." Of the guillotine he states that "it is no longer employed, and is an instrument relegated to the museum-case, though perhaps it does not deserve this, for it cuts the pedunculated tonsils of small children quite well"; of the blunt "reversed guillotine" methods associated with the names of Whillis and Sluder, which are extensively and successfully employed here to remove the tonsil completely in its capsule, he only says that "Sluder has modified the old tonsillotomy, but his method is not applicable to all cases."

Dr. Laurens's book covers the entire field of surgery of the ear, nose, and throat, and is well worth study.

Ear, Nose, and Throat Treatment in General Practice.
By GEORGES PORTMANN, M.D., Professor Agrégé of Oto-Rhino-Laryngology, Faculty of Medicine of Bordeaux. Translated and edited by R. SCOTT STEVENSON, M.D., Assistant Surgeon, Metropolitan Ear and Throat Hospital. London: William Heinemann. 1924. Pp. 180. 10s. 6*d*.

THIS little book deals almost entirely with the drug treatment of diseases of the ear, nose, and throat, and has been made more available to practitioners in this country by the translation of the prescriptions into English weights and measures. The translator has made certain modifications where the accepted British and French opinions on a subject are quite incompatible, and it would, perhaps, have been well to indicate in the text where this has been done; he also draws attention to Dr. Portmann's free use of cocaine, especially in acute conditions, as contrary to British practice. The book is arranged as a list of diseases, each disease being headed by a title and a short description followed by an account of the local treatment advised, and, finally by general treatment. The latter is in general very condensed; little or no indication is given of the rarity of the affection under discussion, nor of its severity, and we are seldom told whether the patient should be kept in bed or allowed to continue his work. It is sometimes difficult to recognise the variety of disease concerned by the title and description in the heading. Under local treatment a large number of prescriptions are given for gargles, "throat baths," paints, and sprays, many of these being frequently repeated with slight variations under different headings; this section is the most valuable feature of the book, and should be useful both to the consultant and general practitioner.

UROLOGY.

Archives Urologiques de la Clinique de Necker.
Published by F. LEGUEU, Professeur de Clinique des Maladies des Voies Urinaires, Chirurgien de l'Hôpital Necker. Vol. IV., Part 1. Paris: A. Maloine et Fils. 1923. Pp. 97.

THIS is a collection of papers by various authors who have worked in Prof. Legueu's clinic. Vaccine treatment of abscess of the prostate is dealt with by P. Fouquiau, who concludes that the disease is rendered less serious and its course shortened by the exhibition of a staphylococcal vaccine. Prof. J. G. Cano describes a new intravenous treatment of gonorrhœa by means of a mixture of methylene-blue and phenol dissolved in an animal serum rich in albumin and globulins. The results show a more rapid cure and a freedom from complications, especially from chronic gleet. Anghel calls attention to ulcerative lesions which are provoked by an indwelling catheter at the penoscrotal angle and gives advice as to how such lesions may be prevented. H. Béclère and B. Fey give an interesting discussion on the differential diagnosis by radiography between stone in the kidney and biliary calculus. Other contributions are: Infection of the Adenomatous Prostate (Astraldi), Peri-Urethral Abscess (Manthopoulo), and Traumatic Rupture of a Varicocele (Astraldi).

SURGICAL HANDICRAFT.

A Manual of Surgical Handicraft and Physiotherapy.
Vol. I. By J. RENFREW WHITE, M.S., F.R.C.S., Assistant Surgeon, Dunedin Hospital; Assistant Lecturer in Clinical Surgery, University of Otago. Dunedin: Coulls, Somerville, Wilkie, Ltd. 1923. Pp. 566–xxi.

THE author states in his preface that he has written his book for junior medical students, but certainly it should be read by residents and practitioners. It resembles in its general arrangement and in subject-matter the usual house surgeons' manual of surgical handicraft, but has special features of its own which render it particularly useful. For example, full instructions are given in the mechanism and use of the autoclave, the administration of enemata, the application of radiant heat, the transport of patients, and the conduct of operations. Special formulæ, which are sometimes difficult to find, are easily discovered by reference to the index and a commendable feature is the author's practice of describing the use of special methods—Beck's paste method, for instance—in the originators' own words. It is probable that in the next edition the author will be able to eliminate a certain number of methods and formulæ which are now falling into disuse.

ORGANIC SUBSTANCES, SERA AND VACCINES IN PHYSIOLOGICAL THERAPEUTICS.

By D. W. CARMALT-JONES, M.D. Oxon., F.R.C.P. Lond., Professor of Systematic Medicine, University of Otago, New Zealand. London: William Heinemann. 1924. Pp. 395. 15*s*.

IN selecting his title Prof. Carmalt-Jones appears to have ignored the fact that drugs of vegetable origin are as much "organic substances" as those derived from the animal kingdom. It is to the latter alone, and in particular to those manufactured from organs known or alleged to have a content of "hormone," to which the first section of the book is devoted. The most vivid resemblance at present discernible between these particular "organic substances" and the equally organic sera and vaccines dealt with in the remaining sections lies in the vast amount of theorising to which they all have given rise, and the frequently doubtful results of their exhibition. A further point in common to "organo-" and vaccine-therapy is that both in the minds of many practitioners are invested with a certain measure of mystery. It is for the practising medical man that Prof. Carmalt-Jones has written, and this last consideration may have weighed with him in bringing his expositions of the two varieties of therapeusis together in one volume.

To the practising physician the author's clear and detailed indications for the exhibition and dosage of the substances with which he deals should prove of very real value, though descriptions of the technique of such procedures as the complement-fixation test and the determination of the opsonic index may be of little interest to the bulk of practitioners, while as given by Prof. Carmalt-Jones they are not detailed enough for the guidance of the laboratory worker. Failure to provide the minutiæ of details of technique cannot, however, be imputed to the author as a general fault; pp. 132 to 138 are devoted entirely to a description of the method of taking blood from a vein for culture, at the conclusion of which the reader is left with a syringe full of blood and no instructions as to what to do with it before it clots. The section on serum-therapy would have been rendered more valuable by a consideration at greater length of anaphylaxis, and by the inclusion of details of the methods for testing for sensitiveness and of abolishing it when discovered. In this connexion it is noteworthy that although the terms "apo-" and "epi-phylaxis" with which Sir Almroth Wright has enriched the language both find places in the index, the more generally recognised "anaphylaxis" fails to do so.

We mention these points that they may be rectified in subsequent issues.

BRITISH GUIANA MEDICAL ANNUAL, 1923.

Edited by F. G. ROSE, M.B., B.C. Cantab. Demerara: Daily Chronicle, Ltd., Georgetown. Pp. 181. 7s.

THIS is a selection of papers presented at the West Indian Medical Conference—most of which reach a high standard of accomplishment. But it is stated that in all probability this issue will be the last, as it is hoped to establish a combined West Indian medical journal. The editor contributes a useful study of the biological characters of the effluents from septic tanks in British Guiana, as well as a paper on the leucocytes in filariasis and the use of vaccines in that disease. There are two papers on alastrim, by Dr. J. R. Dickson and Dr. C. S. Gideon, the general opinion seeming to favour its differentiation from true small-pox, a view not usually held. Dr. Wolff, Government bacteriologist of Dutch Guiana, writes on dermal leishmaniasis in Surinam; Dr. J. Anderson on dysentery, its diagnosis and treatment; and Dr. C. U. Lee submits a report upon the incidence of filarial infection amongst the Chinese and immigrant races in Georgetown. Dr. W. de W. Wishart contributes two papers on public health problems in Georgetown, one dealing with infant welfare. The Editor and Dr. J. E. Chow have written a résumé of scientific work published by medical men in British Guiana from 1769 up to the present day. Various of the short clinical papers now incorporated in this Annual were printed in the Transactions of the British Guiana branch of the B.M.A.

CANCER.

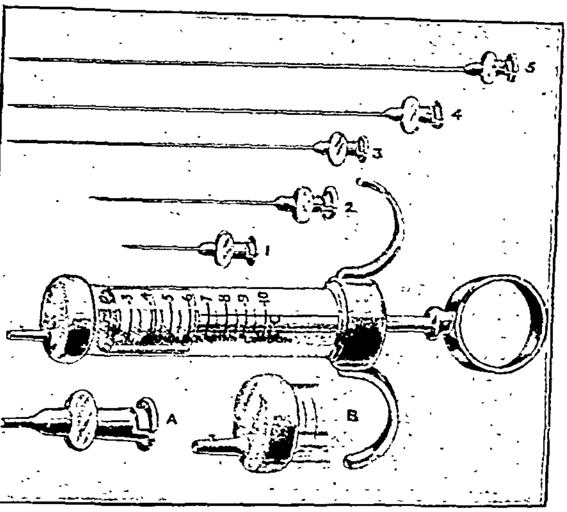
How it is Caused. How it Can be Prevented. By J. ELLIS BARKER. With an introduction by Sir W. ARBUTHNOT LANE, Bart. London: John Murray. 1924. Pp. 432. 7s. 6d.

THE message of Mr. Ellis Barker is that civilised mankind suffers from constipation, chronic poisoning by the chemicals used as food preservatives, and vitamin starvation, and that this is responsible for much ill-health. This is not new, though the author does his best to make it look new by employing in his writings the polemical methods which are effective in dealing with political and economic matters—subjects which have occupied his attention in the past. He then proceeds to argue that cancer being, as he says, a disease of civilisation, is due to dietetic errors inducing chronic poisoning and vitamin starvation. In supporting his view he produces statistical fallacies which have done duty often for this kind of argument. Mr. Ellis Barker is very ill-informed on the subject on which he writes—apparently as a self-constituted authority. If we accepted his statistical fallacies we could use his arguments to prove that cancer is due to an excess of vitamins. For has not in Japan the incidence of cancer increased greatly, while at the same time that of beri-beri has diminished?

New Inventions.

A SYRINGE FOR REGIONAL ANÆSTHESIA INCLUDING SPLANCHNIC ANALGESIA.

THE syringe illustrated has been designed for regional anæsthetic work, including splanchnic analgesia, for which a specially long needle is required. The syringe is of the Record type and is capable of holding 12 c.cm., but is graduated to 10 c.cm. only, the remaining 2 c.cm. being available for aspiration after the syringe has been filled to the 10 c.cm. mark and has been attached to the needle already in position in the patient. The barrel is made of glass so that on aspiration it is possible to see whether blood has entered the syringe, a most vital point in regional anæsthetic work, otherwise the contents of the syringe might be discharged into a blood-vessel.



Syringe for regional anæsthesia. A shows the bayonet fitting enlarged; B, the peripheral nozzle and pin.

The barrel is closed by means of a screw-fitting cap bearing half-rings on either side so that an easy grip is obtained while injecting. The ordinary record fitting is apt to slip and therefore the screw cap was substituted to overcome this disadvantage.

The syringe is made with a peripheral nozzle which greatly facilitates its use in some positions and is especially useful for raising the cuticular wheal with the fine needle before introducing the larger-sized needles through the skin. The nozzle is made with a pin which holds the bayonet fitting with which each needle is made, thus preventing any "flying off" of the needle when injecting. Fig. A shows the bayonet fitting enlarged and Fig. B the peripheral nozzle and pin. The needles are made of rustless steel and are of the sizes recommended in Labat's "Regional Anæsthesia," the No. 5 needle being used for inducing splanchnic analgesia and the No. 1 for raising the cuticular wheal. The sizes are as follows:—

	Length in mm.	Diameter in mm.
Needle No. 1	20	0·6
„ „ 2	50	0·7
„ „ 3	80	0·8
„ „ 4	100	0·9
„ „ 5	120	1·0

The syringe has been made for me by Messrs. Arnold and Sons (John Bell and Croyden Limited), 50-52, Wigmore-street, W. 1, and they supply it in a box containing three of each size of needle.

O. STANLEY HILLMAN, F.R.C.S. Eng.

Middlesex Hospital, London, W.

THE LANCET.

LONDON: SATURDAY, JULY 12, 1924.

THE NATIONAL PHYSICAL LABORATORY.

AT the invitation of the President of the Royal Society, a large company gathered at the National Physical Laboratory on June 24th to visit the research and testing departments. The inspection, an annual event, is greatly appreciated by scientists, for it affords an opportunity of gaining first-hand information about current physical problems from experts who are bent on solving them. The efficiency in routine measurement and activity in research observable in all departments of this laboratory is a valuable lesson in scientific method and industry. In the thermometry section, for example, approximately 15,000 clinical thermometers are tested weekly. Soda-glass instruments show a tendency to fail as maximum thermometers, and this deficiency has made it desirable to detect these instruments quickly. For this purpose an X ray set has been installed. When a trayful of thermometers is passed between the X ray bulb and a fluorescent screen, the greater transparency to X rays of soda-glass instruments renders them easily distinguishable from those made of glass approved by the laboratory.

One of the new features in the radiology department is the testing of materials used in radiotherapy. For measurements of the lead equivalents of protective materials either a balance or a substitution ionisation method is used, the former for protectives equivalent to 0·1 mm. lead and the latter for thicker materials. Stress is laid upon the importance of testing lead-free protective materials at more than one exciting voltage on the X ray tube. Radiographs of commercial ebonite often indicate metallic dust distributed through the material, which renders it valueless for insulating purposes. Facilities have, therefore, been provided for the radiographic examination of materials used in the construction of apparatus. The importance of a preliminary radiographic examination of insulating materials, which would prevent the frequent occurrence of insulation trouble in high tension apparatus, can hardly be over-estimated. We note with satisfaction that the department is now prepared to test all kinds of X ray and electro-medical apparatus. Performance tests on high tension transformers, coils, couches, screening and tube stands are becoming a routine practice, and endurance and efficiency tests are also undertaken. The efficiency of apparatus in current use would appear of secondary importance; for this is seldom known, so that it is common to find apparatus being run far below its maximum efficiency with consequent waste of time and energy. The radiology department will doubtless make a feature of efficiency tests, the results of which may well lead to material improvement in the design and standardisation of X ray and electro-medical apparatus. The fees for the above tests are high, but as the supply of instruments for testing increases, they will be reduced. Considerable experimental work on the methods of obtaining high vacuums has been done at the laboratory, resulting in important technical improvements in existing methods. Annular mercury jet pumps have been constructed in metal which have decided advantages over the usual glass diffusion pumps; these are considerably more efficient, being capable of exhausting at the rate of 7 litres per second, so that a high degree of vacuum can be obtained in a well-prepared X ray tube in a few seconds.

During the past year the department of sound has been extended considerably, and a variety of problems are now receiving experimental treatment. The acoustic features of rooms are being studied by a ripple tank method. A wooden model, based on section drawings of a hall, is laid flat upon the bottom of the tank. The propagation of waves through a room, caused by a mechanical dipper which disturbs the water within the model, may be observed directly or photographed. By this means it is possible to determine what structural alterations to the hall are necessary to remove its acoustic defects. Researches on the photography of sound are also proceeding and some interesting results have been obtained. By the ingenious method of placing two point sparks gaps of different metals in series, the light from one renders visible for a short time the sound disturbance from the other. Experiments on the transmission and reflection of sound by partitions are being conducted in padded rooms. The method adopted is to reflect sound from a loud speaker to the partition under test by means of a parabolic reflector. The properties of the sound issuing in various directions from the partition are then tested by electrical means. Another interesting example of research in applied science is the investigation of the problems of refrigeration which has been begun at the laboratory during the past year. Models of ships holds are made and the temperature distribution in them is measured by a system of thermo-couples. Smoke is used to watch the circulation of air in the hold, which should be efficient to remove the large quantities of carbon dioxide evolved from fruit and to establish a uniform temperature. The question of a packing material suitable for perishable goods is also under consideration, and experimental data are being collected to determine the most suitable substances for this purpose. In this problem the thermal conductivity of the material is an important factor and has been determined for a variety of substances such as expanded rubber and compressed cork.

The advance in research and technique which has been made at the laboratory during the past year has been remarkable, and forms a valuable contribution to our national scientific equipment.

TOWN PLANNING LEGISLATION.

THE two Town Planning Bills (for England and Scotland respectively) have now emerged from Joint Select Committee in amended form, and it may be hoped that they will have an opportunity of becoming law this session. Each of the Bills consolidates the existing legislation (beginning with the Act of 1909) into a convenient document containing 22 sections and four schedules. It would not have been difficult to make one Bill serve for both England and Scotland, a clause being added to comprise such adaptations as are necessary in view of the different central and local authorities in Scotland and in view of the unassimilated details of Scottish administration. Scottish feeling, however, is naturally in favour of having a separate Bill for Scotland, and Scottish influence in Parliament, never negligible, is strong to-day. If these two measures can be passed, we hope that the excellent consolidating Bill which the Ministry of Health has prepared for dealing comprehensively with the law of National Health Insurance will also be given a of technique cannot, however, be imputed to the author as a general fault; pp. 132 to 138 are devoted entirely to a description of the method of taking blood from a vein for culture, at the conclusion of which the reader is left with a syringe full of blood and no instructions as to what to do with it before it clots. The section on serum-therapy would have been rendered more valuable by a consideration at greater length of anaphylaxis, and by the inclusion of details of the methods for testing for sensitiveness and of abolishing it when discovered. In this connexion it is noteworthy that although the terms "apo-" and "epi-phylaxis" with which Sir Almroth Wright has enriched the language both find places in the index, the more generally recognised "anaphylaxis" fails to do so.

We mention these points that they may be rectified in subsequent issues.

British Guiana Medical Annual, 1923.

Edited by F. G. Rose, M.B., B.C. Cantab. Demerara: Daily Chronicle, Ltd., Georgetown. Pp. 181. 7*s*.

This is a selection of papers presented at the West Indian Medical Conference—most of which reach a high standard of accomplishment. But it is stated that in all probability this issue will be the last, as it is hoped to establish a combined West Indian medical journal. The editor contributes a useful study of the biological characters of the effluents from septic tanks in British Guiana, as well as a paper on the leucocytes in filariasis and the use of vaccines in that disease. There are two papers on alastrim, by Dr. J. R. Dickson and Dr. C. S. Gideon, the general opinion seeming to favour its differentiation from true small-pox, a view not usually held. Dr. Wolff, Government bacteriologist of Dutch Guiana, writes on dermal leishmaniasis in Surinam; Dr. J. Anderson on dysentery, its diagnosis and treatment; and Dr. C. U. Lee submits a report upon the incidence of filarial infection amongst the Chinese and immigrant races in Georgetown. Dr. W. de W. Wishart contributes two papers on public health problems in Georgetown, one dealing with infant welfare. The Editor and Dr. J. E. Chow have written a résumé of scientific work published by medical men in British Guiana from 1769 up to the present day. Various of the short clinical papers now incorporated in this Annual were printed in the Transactions of the British Guiana branch of the B.M.A.

Cancer.

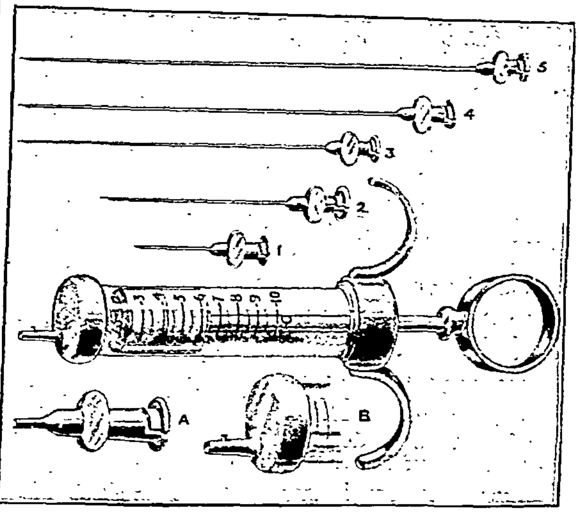
How it is Caused. How it Can be Prevented. By J. Ellis Barker. With an introduction by Sir W. Arbuthnot Lane, Bart. London: John Murray. 1924. Pp. 432. 7*s*. 6*d*.

The message of Mr. Ellis Barker is that civilised mankind suffers from constipation, chronic poisoning by the chemicals used as food preservatives, and vitamin starvation, and that this is responsible for much ill-health. This is not new, though the author does his best to make it look new by employing in his writings the polemical methods which are effective in dealing with political and economic matters—subjects which have occupied his attention in the past. He then proceeds to argue that cancer being, as he says, a disease of civilisation, is due to dietetic errors inducing chronic poisoning and vitamin starvation. In supporting his view he produces statistical fallacies which have done duty often for this kind of argument. Mr. Ellis Barker is very ill-informed on the subject on which he writes—apparently as a *self-constituted* authority. If we accepted his statistical fallacies we could use his arguments to prove that cancer is due to an excess of vitamins. For has not in Japan the incidence of cancer increased greatly, while at the same time that of beri-beri has diminished?

New Inventions.

A SYRINGE FOR REGIONAL ANÆSTHESIA INCLUDING SPLANCHNIC ANALGESIA.

The syringe illustrated has been designed for regional anæsthetic work, including splanchnic analgesia, for which a specially long needle is required. The syringe is of the Record type and is capable of holding 12 c.cm., but is graduated to 10 c.cm. only, the remaining 2 c.cm. being available for aspiration after the syringe has been filled to the 10 c.cm. mark and has been attached to the needle already in position in the patient. The barrel is made of glass so that on aspiration it is possible to see whether blood has entered the syringe, *a most vital point* in regional anæsthetic work, otherwise the contents of the syringe might be discharged into a blood-vessel.



Syringe for regional anæsthesia. A shows the bayonet fitting enlarged; B, the peripheral nozzle and pin.

The barrel is closed by means of a screw-fitting cap bearing half-rings on either side so that an easy grip is obtained while injecting. The ordinary record fitting is apt to slip and therefore the screw cap was substituted to overcome this disadvantage.

The syringe is made with a peripheral nozzle which greatly facilitates its use in some positions and is especially useful for raising the cuticular wheal with the fine needle before introducing the larger-sized needles through the skin. The nozzle is made with a pin which holds the bayonet fitting with which each needle is made, thus preventing any "flying off" of the needle when injecting. Fig. A shows the bayonet fitting enlarged and Fig. B the peripheral nozzle and pin. The needles are made of rustless steel and are of the sizes recommended in Labat's "Regional Anæsthesia," the No. 5 needle being used for inducing splanchnic analgesia and the No. 1 for raising the cuticular wheal. The sizes are as follows:—

	Length in mm.	Diameter in mm.
Needle No. 1	20	0·6
" " 2	50	0·7
" " 3	80	0·8
" " 4	100	0·9
" " 5	120	1·0

The syringe has been made for me by Messrs. Arnold and Sons (John Bell and Croyden Limited), 50–52, Wigmore-street, W. 1, and they supply it in a box containing three of each size of needle.

O. Stanley Hillman, F.R.C.S. Eng.

Middlesex Hospital, London, W.

enough to make it obvious that in this direction alone the method has far-reaching possibilities. He brings forward evidence to show, for example, that mitotic division is not so much the expression of the necessity for cell multiplication as a means by which the cell may adjust itself to altered conditions of environment, and he suggests a valuable field of research for the experimental cytologist. An even more important application of the technique will probably be evolved in the direction of the study of the medium. In other words, cytological studies will not be the only end of "in vitro" cultures, but the growing tissue may serve as a reliable and convenient indicator of the properties of the medium. This implies, of course, a regular and high proportion of successful cultures, and also the possibility of growing tissues in a greater bulk of fluid—in a test-tube, for example. But whatever the future of the method may be, the tissue culture should now pass out of the stage of being a laboratory curiosity and achieve the importance of an experimental technique.

◆

RATIONS FOR THE INSANE.

THE report of the committee on dietaries in mental hospitals, which is abstracted on p. 81, shows that careful and exhaustive inquiry has enabled definite constructive recommendations to be made. The trouble taken by the committee to obtain relevant information on the practical as well as the theoretical aspect of the subject before coming to any conclusion enhances considerably the value of their proposals. As a preliminary measure the committee asked for and obtained copies of the dietary scales then in force in all county and borough mental hospitals. These were carefully examined, amended by correspondence where necessary, and expressed in terms of caloric values; the final results were submitted to the Quantitative Nutritional Committee of the Medical Research Council for an expression of opinion on their prima facie interpretation. A statement was also obtained from medical superintendents of mental hospitals as to the cost of all such dietaries. Taking as the basis for consideration the accepted food requirements for normal adults, the committee then proceeded, by obtaining anthropometric measurements and other data, to ascertain how far these quantities were applicable to a population of persons suffering from mental disorder; subsequently checking the conclusions by special experiments in basal metabolism, made at the Middlesex County (Springfield) Mental Hospital. Such oral evidence on definite points, as seemed necessary, was then obtained from various sources as—the medical superintendents of some mental hospitals; clerks and stewards deputed for this purpose by the Association of Clerks and Stewards of Mental Hospitals; from the persons in control of kitchens in general hospitals; from the managers, engineers, and cooks of large catering concerns, and from firms supplying kitchen equipment. Visits were paid by the committee, or by some of its members, to a number of mental hospitals, to the kitchens, stores, and cold storages of certain general hospitals, and to modern catering establishments. The chief reasons for these visits were to inquire into the value of certain varying methods in force in different institutions, and to acquire knowledge generally regarding kitchen equipment, the preservation of food, its preparation for table in large quantities, and the means adopted for its distribution whilst hot to considerable numbers of persons. A member of a well-known firm of domestic engineers, who is thoroughly conversant with the apparatus now employed in the preparation, cooking, and distribution of food in mental hospitals in England and Wales, was, moreover, instructed to inquire into arrangements for food preparation and distribution in current use in America and Canada in these hospitals. A model dietary which seemed to meet requirements and be free from the defects in existing scales was then prepared and circulated to the medical superintendents of all mental hospitals with a request for suggestions and estimates of the cost of adopting the model dietary. Detailed replies were received from all of the 95 superintendents to whom the circular was addressed, and were surprisingly divergent. A more exact estimate, founded strictly upon contract prices in force on March 20th, 1924, was obtained from the authorities of a mental hospital in the London district, where more than 1400 persons are fed entirely on food purchased from outside, no home produce being used. The conclusion as to the maximum cost of the diet (8½*d.* and 8¾*d.* per head per day respectively for country and borough mental hospitals) is thus founded on sound premisses. We congratulate the committee on having succeeded in their object of suggesting a dietary that shall be sufficiently adequate for the maintenance of health and vitality and at the same time be a practical proposition.

Annotations.

"*Ne quid nimis.*"

NATIONAL HEALTH INSURANCE: APPOINTMENT OF A ROYAL COMMISSION.

THE appointment of a Royal Commission on National Health Insurance was announced on Monday last with the following terms of reference: To inquire into the scheme of National Health Insurance established by the National Health Insurance Acts, 1911–1922, and to report what, if any, alterations, extensions, or developments should be made in regard to the scope of that scheme and the administrative, financial, and medical arrangements set up under it. The constitution of this Commission is as follows: Lord Lawrence of Kingsgate (chairman), Sir John Anderson, Sir Humphry Rolleston, Bart., Sir Alfred Watson, Sir Arthur Worley, Sir Andrew Duncan, Mr. A. D. Besant, F.I.A., Mr. F. Bramley, Prof. Alexander Gray, Miss Gertrude Tuckwell, Mrs. Harrison Bell, Mr. James Cook, Mr. John Evans, and Mr. William Jones. The secretary of the Commission, to whom all communications should be addressed, is Mr. E. Hackforth, of the Ministry of Health, Whitehall, S.W. 1, and the assistant secretary is Mr. J. W. Peck, C.B., of the Scottish Board of Health. The Commission is fairly representative of the interests concerned, but the President of the Royal College of Physicians of London is the solitary representative of medicine. Mr. Digby Besant has an actuarial experience of medical affairs which make his presence on a Commission very apt.

DISTEMPER.

AN interim report of the activities of the Council for the Study of Dog Distemper was recently issued to the press by Sir Theodore Cook, the hon. secretary. It would appear from the report that the long preparation for the study of distemper is now completed. Buildings for the breeding and rearing of puppies, a hospital for the treatment of dogs suffering from distemper, and a new and properly equipped laboratory have been erected. The last half-yearly report of the Distemper Council intimated that the arrangements for producing "clean" puppies for experimental work were in the hands of Major G. W. Dunkin, M.R.C.V.S., and Prof. J. B. Buxton, F.R.C.V.S. It is now announced that the new laboratories are in the charge of Dr. W. E. Gye, who will be responsible for the experimental work. The enterprise will be watched with the greatest interest by the medical profession. Dog distemper is such a highly contagious disease that only by the most elaborate precautions and by the exercise of the utmost care can the spread of infection be prevented. Previous workers have sometimes had their investigations ruined by accidental or "spontaneous" cases of distemper occurring in control animals; they have all been hampered by the difficulty of obtaining chance of gaining the Royal Assent before the summer holidays, and that the other consolidations dealing with housing and public health will be pressed forward.

The science of town planning has somehow not yet come into its own. The Review of Legislation in 1922, recently published by the Society of Comparative Legislation, shows no great development of town planning in the legislation of the British Dominions overseas. The State of Victoria set up in 1922 a Metropolitan Town Planning Commission with a duration limited to three years and an expenditure limited to £7500. The Commission is directed to inquire into and report upon the conditions and tendencies of urban development and to make recommendations for its future guidance in consultation with the municipalities and public authorities concerned. Its scope is wide, as it is to examine not only roads, traffic and transportation, and water-front and river improvement, but also food supplies and general amenities. The State of Western Australia legislated about rights in light and air. More than 20 years ago Western Australia revolted from the English Common Law and boldly abolished the acquisition of easements of light and air by prescription; grants of such easements were to be restricted to periods of 21 years. In 1922 the restriction was altered. Grants for longer periods were made possible with the written approval of the governor, but no grant is to prevent the erection of a building on the alignment of a street to a depth of 12 feet. After all, even if there is often something irritating about the system of asserting prescriptive rights, light and air are worth preserving. There is, fortunately, less heard at the moment of the architectural experts who want to abolish the London Building Acts and fill the city and metropolis with sky-scrapers. London has afforded few chances of town planning since WREN produced his scheme for rebuilding the area devastated by the Great Fire. If Great Britain is already too congested to give the town-planning expert the opportunities which await him in more spacious countries, the dwellers in our cities must be content with minor mercies. The Public Health (Smoke Abatement) Bill, now being introduced in the House of Lords by the Earl DE LA WARR, may do something to enhance municipal amenities.

◆

RECENT DEVELOPMENTS IN TISSUE CULTURE.

IT is a remarkable thing that although the possibilities of tissue culture were demonstrated more than 20 years ago, the technique has hardly emerged from the experimental stage. We do not yet know whether we have in the method a means of solving certain fundamental biological questions which other lines of investigation have failed to answer, or merely a barren though brilliant laboratory technique. Many workers, of course, have successfully cultivated tissues outside the body, and it would seem that with proper precautions such cultures may be propagated practically for ever. The histological structure of the culture may be modified by various means, and its rate of growth accelerated or diminished; but beyond these somewhat primitive observations it is disappointing to record that very little has emerged. The technique is undoubtedly tedious and difficult; but all was not plain sailing for the early bacteriologists, and one cannot help feeling that in their attitude towards "in vitro" culture biologists have exhibited something of that "lag" which is so familiar in the cultures themselves. Fortunately there are indications that this period of neglect is at an end. The conviction is steadily growing that tissue culture is a really valuable experimental method, one which should be a commonplace in every pathological or biological institute, rather than a field of endeavour for the more adventurous pioneers.

Mr. T. S. P. STRANGEWAYS has placed laboratory workers under a debt of gratitude, for in two recent publications[1] he has, as it were, lifted the veil of mystery and placed the technique of tissue culture on a sound practical footing. In these little books he describes the method of carrying out tissue culture and some of the results he has obtained. In the book on technique he discusses, with admirable clearness and with the utmost attention to detail, every step in the manipulation necessary to procure satisfactory cultures. No point is too small to escape his notice; in fact, at times he seems to border on the meticulous. But it may be supposed that he does not write thus without very good reasons. In his preface he says: "The beginner will doubtless be tempted to modify the technique recommended in this work, especially if after a few trials he fails to obtain satisfactory results. The writer would, however, urge him to wait until he has succeeded in cultivating tissues by the methods described before he attempts any original improvements." And it is not difficult to read between the lines. Any variations in technique, if they are to be of value, must be the outcome of an accurate and practical knowledge of the methods now in vogue. Such knowledge is obviously possessed by Dr. THOMAS LUMSDEN, who in this issue of THE LANCET draws attention to what appears to be an extremely satisfactory method of growing tissues in vitro. Instead of using plasma or an artificial synthetic solution as his culture medium he employs serum, with excellent results. He has been successful where others have failed because he has recognised that the pH of the medium is of the utmost importance, and that serum rapidly becomes impossibly alkaline on exposure to the air by the loss of CO_2. By avoiding such exposure, the pH of serum remains below the necessary limit of 7·7, and tissues will grow in it with great readiness. The importance of Dr. LUMSDEN'S work is undoubted, for it has long been obvious that a profound simplification of the technique would be a necessary preliminary to the general adoption of tissue culture as a routine method of investigation rather than as an end in itself. No laboratory procedure which requires a minimum apprenticeship of four months can ever become popular, nor on the face of it would such a prolonged training seem necessary. After all, the basis of the method has been firmly established in the last few years. All authorities insist upon the necessity for the most rigid asepsis, but this should not be so difficult to achieve. Our modern medical curriculum must be gravely at fault if, at the end of it, the theory and practice of asepsis are not so deeply ingrained in the student as to become a second nature to him. Ordinary technical skill, combined with a sound laboratory training, should fit anyone to undertake tissue culture work; and though success may come to some investigators more easily than to others, we cannot believe that it is not within the reach of all.

In the second of his recent publications Mr. STRANGEWAYS deals with some of the more important observations he has made on the growth and behaviour of the normal cell, and the cell modified by various agencies, in cultures outside the body; and he tells us the dogs fell to 32·3° C., or, on the other hand, rose to 42·5° C., were not productive of serious mischief, and after the animal's return to its stall at 27°–28° C., the body temperature quickly regained its approximate normal. A rise of temperature (vaginal) reaching 43·2° C., productive of delirium, profuse salivation, and acute symptoms of distress, was yet rapidly recovered from on removal to cool surroundings. It would seem, therefore, that even in high paraplegia, thermometry at somewhat frequent intervals can, as M. S. Pembrey has pointed out, notify over-stress of thermotaxis in ample time for the taking of successful measures of relief.

THE PAPWORTH VILLAGE SETTLEMENT.

AN extension of the Papworth Village Settlement was declared open on Tuesday last by the Duke and Duchess of York when a large and representative company were present. The Settlement is the practical realisation of a scheme which in its inception seemed highly imaginative or Utopian, and its value may lie as much in the example which it sets to other communities as in the practical good which it has been able to do for a certain number—now quite a large number—of sufferers from tuberculosis. The objects and the activities of the Papworth Village Settlement have been frequently noted in these columns as well as in the lay papers, and we may assume that they are quite familiar to our readers; but that sort of familiarity is as nothing compared with the appreciation of the work which will follow a personal visit. We strongly recommend anyone who has the opportunity to make an inspection of the Settlement to seize it and acquaint himself with the all-round manner in which a class, that may be among the unhappiest which modern sociology knows of, can live active and healthy lives and earn good wages, if the initial safeguards are provided, and the risks of protracted unemployment are removed. Dr. P. C. Varrier-Jones, who may be addressed at Papworth Hall, Cambridge, will give every facility for inspection, and previous reference to the description of the movement, written by him and Sir Clifford Allbutt in our columns, will be found a useful preparation for a visit (THE LANCET, Oct. 20th, 1923, 913). At the annual conference of the National Association for the Prevention of Tuberculosis, it will be observed from our report this week that the Papworth Village Settlement is regarded by experts as an acknowledged success.

THE CONDITIONS OF INDUSTRIAL EFFICIENCY.

THE Industrial Fatigue Research Board has acted wisely in publishing a short summary[1] of the conclusions arrived at in the various reports issued by the Board during the past six years. Results obtained in specific investigations tend to be forgotten, except by those interested in the particular industry, and may escape even their notice. Yet they form, when taken together, an organic whole, as may be perceived from this summary, with at least one common factor—human activity. The industries from which results have been culled include the great textile group, the metal industries, boot and shoe making, pottery manufacture, the glass and laundry trades, and repetition work. The findings are subgrouped according to (*a*) working conditions, (*b*) working methods, (*c*) administrative matters. The accumulated evidence goes far to establish that maximum output is contingent on maximum fitness of the individual worker, and that this can only be attained by providing the most hygienic and comfortable conditions and methods of work. Indications of the ways to effect at any rate improvement arise from each study. The recommendations are of different kinds. Some merely suggest promising new fields of research in which no work has yet been carried out; others advocate the adoption of certain practices with a view to the accumulation of useful data; others, again, deal with the applications to industry of the results already disclosed. Most of the recommendations have been put forward with the concurrence of representatives of the industries concerned, and it is hoped by the Board that these industries will give careful consideration to the question of giving them practical effect. Analysis of the investigations of the Board grouped by subject-matter—i.e., ventilation, lighting, or noise—is needed to establish clearly the law and order of the conclusions; such analysis is contemplated by the Board and its appearance will be welcomed.

SPECTACLES FOR SHOOTING.

THE article which we publish in another column on vision and target shooting by Mr. Wynn Wirgman explains the optical problem of correcting an error of refraction in a rifle shooter who lies in the ordinary prone position and shoots with his right eye. In this position the line of sight passes not through the mathematical centre of the correcting lens but through a point in its upper and inner quadrant. The result is that, owing to the prismatic effect of the lens, the image is displaced, and when the error of refraction is as much as five dioptres, as in some of the author's cases, the displacement may be considerable. Hence it is necessary to centre the glass so that the line of sight passes through the optical centre. To prevent distortion it is also necessary to ensure that the plane of the glass is parallel with that of the target. It is of interest to read that, acting on these principles, Mr. Wirgman has prescribed glasses for as many as 38 men who have been or are really good shots. Of course, for ordinary purposes these glasses would be quite unsuitable. The correction of refraction is thus not always the merely mechanical problem that it is sometimes supposed to be.

ANALYSED MORTALITY.

AT a meeting of the Faculty of Actuaries on June 30th Mr. Eric B. Nathan, F.I.A., read a paper entitled Analysed Mortality: The English Life Tables No. 8A. Using the census data (England and Wales) of 1911 and the deaths registered in 1911 and 1912, Mr. Nathan has constructed for each sex separately the rate of mortality (q_x) curve for each of 20 groups of diseases. It is therefore possible to display graphically the share of each group in the total mortality at any age and to follow the change in importance of each group throughout life. The curves are of much interest as some of the groupings have not been adopted before, and so detailed a study of the data derived from a short period is not available. Mr. Nathan does considerably less than justice to the General Register Office when, speaking of pulmonary tuberculosis and cancer, he remarks that "my attention was brought to the fact that even to-day there was no definite measure of the mortality due to these two scourges of the youth and middle ages of the people of this country, although partial investigations had been made, such as those of Messrs. Teece, King, and Newsholme, and more recently those of Dr. Brownlee and Profs. Karl Pearson and Arne Fisher." As a matter of fact, rates of mortality at ages in quinquennial groupings for tuberculosis, pulmonary and other forms, and for cancer, with distinction of sites, have been regularly published by the Registrar-General and commented upon by Dr. T. H. C. Stevenson for many years. It is true that in official publications the rate of mortality used is what actuaries term the Central Death Rate, and the rates have not been smoothed or graduated. But the actuary's Rate of Mortality can be easily deduced from the Central Death Rate (except at the ends of life, it does not differ from it very substantially in magnitude), and there are not many medico-statistical purposes for which a graduated function is essentially superior to the crude rates. So far, indeed, as tuberculosis and cancer an adequate supply of healthy puppies which had not suffered from distemper and had never been exposed to the risk of infection. It is indeed probable that the first generation of puppies, reared under conditions which exclude the possibility of distemper infection occurring, will not prove entirely satisfactory. An inheritance of partial immunity may well complicate the experimental study. The second and later generations become progressively more susceptible to the disease and consequently are more suitable for the work in hand, but it will take a long time to obtain such puppies. Patience is thus demanded even for the provision of material for study—the routine part of the work. The real difficulties will begin with the attempts to isolate the causal organism. It is commonly believed that the organism belongs to the group of "filter-passers," but this is by no means certain, as recent work in Japan[1] has shown. The first step in the research must be to show conclusively whether the distemper virus is filterable or not. The tedious, but necessary, preliminaries to this task appear to have been overcome; the laboratories and kennels are well equipped, through the generosity of the subscribers to the Field Distemper Fund, and the work is being carried out under the best possible auspices with good chances of success. May good fortune attend it.

---

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

THE fifth annual general meeting of the Society was held on July 10th, Sir Auckland Geddes presiding, in succession to the late Lord Willoughby de Broke. In an interesting address outlining forcibly the necessity for a regulated frankness especially at the educational period with reference to venereal disease, Sir Auckland Geddes indicated the value that might accrue from the union of the Society with the National Council for the Control of Venereal Diseases in one strong body, but he said that the value of such a union would be damaged if the result were "to diminish the weight of the attack on the causal organisms of venereal diseases." He then moved a resolution embodying a request to the Ministry of Health for the allocation to the Society of a fair share of any money set aside for the education of the public regarding venereal diseases and their prevention. Mr. Wansey Bayly then laid before the meeting details of the work of the Society during the past year when other members of the executive present spoke from various points of view as to the work of the Society and the need for its official recognition.

TEMPERATURE REGULATION AFTER SPINAL TRANSECTION.

A CONTRIBUTION by Prof. C. S. Sherrington, P.R.S., to the current number of the *Journal of Physiology*, modestly entitled Notes on Temperature after Spinal Transection, with Some Observations on Shivering, contains amongst other matters important observations on impairment of temperature regulation in paraplegic dogs which for other reasons were kept for relatively long periods. Severance of the spinal cord was in every case performed under deep anæsthesia and with full precautions against sepsis. In some animals the spinal transection was situated as far forward as the cervical region. The impairment of thermotaxis remains severe long after complete subsidence of the acute symptoms of "spinal" shock. A normal dog, lightly anæsthetised and immersed up to its middle in ice-cold water for 10 minutes, showed a fall of mouth temperature from 37·6° to 37·2° C. A small dog similarly immersed 530 days after spinal transection (first thoracic level) showed a fall of mouth temperature from 37·9° to 33·9° C. Immersion under the same conditions of an unanæsthetised normal dog of 4 kilos weight brought the mouth temperature from 37·9° down to 37·2° C. in 18 minutes, while a repetition of the procedure on this same dog 30 days after spinal transection at the sixth thoracic segment brought the mouth temperature from 37·5° down to 35·8° C. in 18 minutes. It is known that the degree of impairment of thermotaxis in paraplegia is proportioned to the extent of the paralysis—i.e., is greater the further forward the seat of spinal severance. Experiments are quoted in detail upon dogs with severance at levels between the seventh cervical and third lumbar, and at periods subsequent to the transection varying from 21 days to 589 days to exemplify this relationship. As to cold shivering in the paraplegic dog, von Goltz considered the shivering to be spinal. Charles Richet, however, in 1893 noted that in the chloralised dog severance of the spinal cord at once confined the field of shivering to muscles headward of the spinal transection, and concluded that shivering requires a pre-spinal nervous mechanism. Sherrington and Laslett in 1903 instanced a dog retaining excellent health for 580 days after exsection of the eighth cervical spinal segment, in which free shivering, when the dog was cooled, occurred headward of the lesion, but no trace of shivering ever trespassed backwards to the muscles innervated from behind the lesion. Shivering in other dogs was absent from the paraplegic region as completely a year and a half after spinal severance as at first, and was so although the usual spinal limb and other reflexes, cutaneous and deep, were brisk and the femoral pressure as high as 122 mm. Hg. The non-appearance of cold shivering in the paraplegic region of the dog can reveal with great clearness the exact segmental level of the spinal lesion by demarcating the muscle field innervated behind the lesion from that in front—indeed, the boundary will actually subdivide an individual muscle—e.g., the anterior part of the deltoid will shiver violently when in its posterior part no shivering can be evoked. In paraplegic man also shivering fails below the lesion and could exhibit the segmental level of a traumatic lesion. Spinal transection impairs the dogs' adjustment to heat as well as to cold. The absence of heat-sweating in the paraplegic region is well known, although profuse sweating unrelated to heat may occur in the paraplegic region in patients as a spinal reflex. Summing up what he calls "these admittedly desultory observations," the author finds that in dogs long after complete subsidence of spinal shock, as judged from usual post-transection reflexes, there persists in the region innervated from behind the transection marked failure of adjustment of the surface blood-supply (paws, *pinnæ*, nose) to changes of surrounding cold and warmth. The failure of this vascular adjustment, though not absolute, remains severe and without improvement; along with it there is complete abeyance of sweating to heat and in muscles complete abeyance of shivering to cold. Diurnal fluctuations of 2° C. in the stall temperature affected conspicuously the vaginal temperature of cervical paraplegic dogs fully removed from spinal shock. In dogs all attempts, even after considerable exposure, to induce cold shivering in the paraplegic region as a spinal reflex entirely failed. On cold immersion of the insentient paraplegic portion of the dog, shivering occurred headward of the spinal lesion even when the skin headward of the lesion still felt, to the touch, fully "warm." Shivering under these circumstances is, on older views of the nature of the adequate skin-stimulus for "cold" difficult to explain as a reflex, but it is not precluded from being reflex on the views propounded by Ebbecke (1917) for the nature of the adequate skin-stimulus for "cold" sensation. On the other hand, shivering under these circumstances may be possibly of deep origin from direct cooling of a central (diencephalic) thermotaxic mechanism. Shivering seems not to require the afferent nerves of the lung or of the shivering muscles. Shivering reflex or "central" requires, like Richet's heat polypnœa, some central nervous mechanism anterior to the mid-brain. Instances where, under severe but short-lasting changes of surrounding temperature, the body temperature (vaginal) of household, fire, and motor car insurances; and with regard to the last, a special service now offered by the Agency has met with considerable approval. A tentative agreement between the Agency and Messrs. Mann, Egerton, and Co., Ltd., has been arrived at, by which that well-known firm places its services at the disposal of doctors insuring through the Agency; and as this scheme develops, and members become aware of it, what is now a promising start in the way of placing a reliable motor service organisation at the disposal of the M.I.A. will develop into a substantial bureau of advice to that large and increasing number of doctors who find the use of a motor car essential to their work. The rebates to doctors insuring through the Agency amounted during the year 1923 to over £2000, and the surplus from the income and expenditure account stood at the end of the year at £1595 14s. Interim grants amounting to 750 guineas were made to the Royal Medical Benevolent Fund (£210), the Royal Medical Benevolent Fund Guild (£210), Epsom College Benevolent Fund (£105), and the Royal Hospital and Home for Incurables, Putney (£52 10*s.*). A sum of £210 was added to the Educational Grants (Girls) Fund. As a result of this distribution, the total sum subscribed to medical charities by the Medical Insurance Agency since 1910 has reached £12,250.

TREATMENT OF ECLAMPSIA.

WE would call the attention of practitioners to the offer made by Prof. B. B. Stroganoff on p. 62 to give his services by day or by night during the next six weeks in treating any cases of eclampsia by his well-tested method. In the last 253 patients treated by this method only six deaths supervened, and these were in cases neglected before the method was applied. Senior members of the obstetric staff of general and special hospitals have already been informed of Prof. Stroganoff's readiness to treat cases, and also members of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine who live in London. Prof. Stroganoff's address is 98, Philbeach gardens, Earl's Court, and his telephone number is Western 2029.

R.A.M.C. WAR MEMORIAL FUND.—The General Committee of the Royal Army Medical Corps War Memorial Fund will meet at the War Office (Room 219) on July 17th at 4.45 p.m., to decide as to the final disposal of the balance of the Fund.

INTERNATIONAL CONFERENCE ON TROPICAL HEALTH PROBLEMS.—Sir W. Arbuthnot Lane, Sir William Simpson, Sir Leonard Rogers, Sir James Kingston Fowler, and Dr. Aldo Castellani will attend this Conference, which is to be held at Kingston, Jamaica, from July 23rd to July 31st.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—At a meeting of the board of the hospital, Prince Arthur of Connaught in the chair, on June 2nd, the Dean, Mr. A. E. Webb-Johnson, announced that the sum of £20,000 had been given by Mr. Samuel A. Courtauld to endow the University professorship of anatomy in the medical school of the hospital.

INDEX TO "THE LANCET," VOL. I., 1924.

THE Index and Title-page to Vol. I., 1924, which was completed with the issue of June 28th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

THE LANCET OF FEB. 2ND, 1924.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXIX.—THE TREATMENT OF CEREBRAL VASCULAR LESIONS.

THE term "apoplexy," if used in its classical sense, denotes a state of unconsciousness with complete paralysis, except of the vital functions, developing more or less suddenly as the result of blockage or rupture of a cerebral artery. Its onset is sometimes instantaneous, but is usually preceded by premonitory symptoms, such as headache, giddiness, abnormal sensations in or weakness of a limb, or disturbance of speech, which may last for a few minutes or days. Consciousness may be lost slowly or rapidly. The patient lies in a state of coma, breathing stertorously, with a pale or cyanosed face and flaccid limbs. He may never recover consciousness, death occurring quickly or within two or three days. Recovery when it occurs is gradual and is marked by a stage of irritability in which the patient resents interference of any kind. Ultimately he is left with some gross disturbance of function, most commonly hemiplegia.

The apoplectic attack may, however, be less severe and consist of little more than momentary loss of consciousness or giddiness, associated with hemiparesis or aphasia which may disappear in a few weeks.

Sometimes coma supervenes after paralysis has appeared, and frequently a stroke consists solely of a slowly developing hemiplegia that may become complete without any disturbance of consciousness. To an attack such as the latter the term "apoplectic" should not strictly be applied, but the original meaning of the word is now rarely adhered to. The majority of apoplectic seizures occur in patients over 40 who are suffering from arterio-sclerosis with or without arterial hypertension, cardiac hypertrophy, and renal disease. Hæmorrhage or thrombosis is the immediate cause, and one of the branches of the middle cerebral is most commonly affected. A stroke occurring in a young adult is very frequently due to syphilitic arteritis, and sometimes to embolic occlusion or rupture of a basal aneurysm.

Theoretically, it would seem to be important for the proper treatment of vascular lesion of the brain to differentiate cases of hæmorrhage from those of occlusion especially by thrombosis. And the matter might not appear to present any difficulty when the state of the heart and blood pressure can be used as an index. But pathological experience teaches that in many cases, perhaps the majority, it is impossible at the bedside to be certain of the nature of the lesion. In general, embolism is usually the cause in young people with simple or infective endocarditis; between the ages of 20 and 40 thrombosis from syphilitic arteritis is most common, and after 40 either thrombosis or rupture may occur. With embolism or hæmorrhage the onset is usually sudden in a patient with high blood pressure, hypertrophied heart, or renal disease, whereas thrombosis often develops slowly with premonitory symptoms lasting perhaps for hours and frequently occurs in the night. But the lesion may be thrombotic when the left ventricle is hypertrophied, the pulse is full and bounding, and the blood pressure is raised; on the other hand, it may be hæmorrhagic when these signs are absent. Nor is the mode of onset a sure guide, for with thrombosis, while the development of the seizure is usually slow, it may be apoplectiform, and with a small rupture the opposite may occur. The broad rules of treatment should therefore have a general application whatever the immediate cause of the vascular lesion may be.

General Management.

For a patient who is in an apoplectic seizure, or who has the slightest warnings of one, absolute rest is the are concerned, Mr. Nathan's results have been rendered obsolete by official publications. This is not to say that Mr. Nathan's paper is untimely or uninteresting. In fact, it presents important data in a light which will be novel, but quite intelligible, to many medical readers and should receive the special consideration of the medical advisers of assurance offices.

THE STRUCTURE OF ENAMEL.

THE structure of human enamel has attracted much attention from dental histologists and has aroused much controversy. In the past the view has been generally held that enamel was an entirely inorganic tissue, and therefore could only play a passive rôle in the production of dental caries. Latterly it has been suggested that enamel may not be so devoid of organic matter as had been thought and that it might conceivably play an active part, either in predisposing to dental caries or in aiding the individual to resist the disease. The extreme hardness of this tissue has made its investigation one of much difficulty; histological evidence appeared to show that its organic content, if it existed at all, must be extremely slight. On the chemical side, the work of C. S. Tomes was accepted as indicating that organic matter was absent. Against this must be set the more recent work of Lovatt Evans, who, using the most modern analytical methods, found that enamel contained from 1 to 2 per cent. of organic matter. Hitherto it has only been possible to prepare sections of enamel by grinding. In the hands of Leon Williams some wonderful results were obtained, but it is obvious that such a method would fail to reveal any organic structure, if such really existed. The latest histological investigation by H. C. Malleson,[1] marks a notable advance in microscopical technique, for he has been able to decalcify enamel and to cut sections on a microtome after embedding in celloidin. Malleson finds that either citric acid or trichloracetic acid to which alcohol is added, allows the enamel to be decalcified without destroying its structure. The process is a long and tedious one, but the results are of great interest, for sections prepared in this way show a different structure from ground specimens. As is well known, enamel consists of prisms embedded in a small amount of cementing substance. Malleson finds that after decalcification a prism cuticle remains. This surrounds the prisms, and in transverse section is oval in shape with evidence of a longitudinal groove. This cuticle stains deeply with hæmatoxylin and is considered by Malleson to be organic in nature. Whether this interpretation is correct or not, the work marks a notable advance in histological technique, and should materially aid further investigation of the enamel. A study of the micro-photographs as well as of the actual sections, suggests that if Malleson's view be correct, the amount of organic matter must be considerable, far more than 1 or 2 per cent. That does not invalidate Malleson's view, though it suggests the possibility that even prolonged immersion in acid by his method may not entirely remove the lime salts, and that some of the residue may still be inorganic.

TYPES OF PNEUMOCOCCI IN NORWAY.

IN the May number of *Norsk Magazin for Laegevidenskaben*, Dr. T. Thjötta and Dr. O. Hanneborg have published an interesting comparison between the distribution of the various types of pneumococci in the U.S.A. and in Norway. With regard to the former country, it may be remembered that the work of the Rockefeller Institute in New York showed type I. to be present in 33·3 per cent., type II. in 29·3 per cent., atypical type II. in 4·2 per cent., type III. in 13 per cent., and type IV. in 20·3 per cent. The Norwegian investigators have followed the same technique as that of the Rockefeller Institute's hospital, and have employed sera provided by this hospital and the New York Board of Health. In the course of a couple of years they examined the sputa of 100 cases of pneumonia and they found type I. in 44 per cent. of their cases, type II. in 32 per cent., type III. in 6 per cent., and type IV. in 17 per cent. It will thus be seen that the numerical proportion of the various types of pneumococci is approximately identical in the two countries. In the Norwegian material there were only eight deaths, and this mortality of 8 per cent. is in striking contrast to the mortality of 30 per cent. recorded in the U.S.A. before serum treatment was started at the hospital of the Rockefeller Institute. The Norwegian figures are, of course, too small for such a comparison to be fair. With regard to the virulence of the various types, the Norwegian investigators confirmed the observations made in the U.S.A. that type III. must be considered the most dangerous; in the Norwegian material it was responsible for a mortality of 16·6 per cent., whereas the mortality for type I. was only 9 per cent., and that for types II. and IV. only 6 per cent. Fortunately, type III. is comparatively rare, and it is type I. which, owing to its relatively great frequency, plays a most important part both with regard to mortality and complications. In the Norwegian material 11·3 per cent. of the cases of pneumonia, caused by type I., were complicated by empyema—a complication not once seen in the cases of pneumonia in which type III. was found. Dr. Thjötta and Dr. Hanneborg have also studied the mortality rates from pneumonia in Norway since 1876, and they have come to the conclusion that the average is about 15 per cent. It is interesting to note that the yearly fluctuations of these rates throughout the country were much greater in individual hospitals—even large hospitals—than in the whole country; the hospital rates ranged from 10 to 34 per cent., whereas throughout Norway they ranged only from 13 to 18 per cent. It would be interesting to learn the reason for the mortality from pneumonia being approximately twice as high in the U.S.A. as in Norway. May it be that the stationary and homogeneous population of Norway is more resistant than the migrant and heterogeneous population of the U.S.A.? Dr. Thjötta and Dr. Hanneborg suggest that light might be thrown on this matter if information could be obtained as to the mortality from pneumonia among Norwegians settled in the U.S.A.

THE MEDICAL INSURANCE AGENCY.

A MEETING was held of the Committee of Management of the Medical Insurance Agency on June 26th, Dr. R. Langdon-Down being in the chair, in the absence through illness of Dr. G. E. Haslip. The secretary of the Agency, Mr. L. Ferris Scott, presented the audited balance-sheet for the year ended Dec. 31st, 1923, with the chairman's report, and a detailed statement made of the progress of the Agency during the last eight years. The report showed that the Agency had been able to live up to its record of introducing over £100,000 worth of new business per annum, a record established now four years ago; for in 1923 life assurance policies, totalling £101,097, were obtained, the money being assured under 102 policies, and representing a yearly premium income of over £5000. It will be of interest to those who have not happened to watch the activities of the Agency from the beginning to learn that the total sum assured through its medium, since its inception, amounts now to over three-quarters of a million sterling. The continuance of the progress in the premium income of the Agency was shown in the report by the following figures: In 1907–08 the premium income was about £1000; in 1914 it had reached £11,000; in 1922 the figure had increased to £38,000; and in 1923 the net premium income was £47,823. These are big figures for an Agency which confines its activities to one profession. An increase of business was shown during the year in the combined

Special Articles.

VISION AND TARGET SHOOTING.

BY C. WYNN WIRGMAN, M.D. LOND., F.R.C.S. ENG., T.D.,

LATE OPHTHALMOLOGIST, 17TH GENERAL HOSPITAL.

THE sport of rifle-shooting is by no means so popular in the British Isles as in the Overseas Dominions. There are several reasons that may be suggested, but no doubt the principal one is that Government encouragement is lacking. In the Dominions, Government support is hearty, and in consequence many more enthusiastic rifle shots are to be found. Still, there are many here who are constant visitors to Bisley, and the "King's" winner is a person of some small consideration. I therefore venture to make a few observations on the subject of sight in rifle-shooting and the special requirements for shooting spectacles.

The Essentials of Marksmanship.

Attainment of a high standard of marksmanship results from a combination of physical qualities, to which must be added certain mental characteristics as well. The public believe that good eyesight is the one great factor, but in this they are not quite accurate. Ability to see the object aimed at is certainly necessary, but not perfect vision. Fatigue of the eye, I think, and not bad definition, is the main cause of the difficulty in scoring well for a number of consecutive shots, as required in present-day competitions. I have had the opportunity of examining the eyes of many of the Bisley competitors, and it is upon these observations that this note is based.

Many of the younger men, although not emmetropic, do not feel the need of glasses so much, because fatigue is not so easily felt in youth where the application is not constant and intense. In Bisley shooting there is an interval for rest between each shot, possibly as much as two to three minutes when three competitors are firing at the same time.

Visual Defects in Shooters.

I have prescribed spectacles for 38 men who have been, or are, really good shots. Of these I find 22 were hypermetropic, 15 needing spheres only, and 7 cylinders with or without an additional sphere; 10 were myopic, and all but one of these needed cylinders as well as spheres: 6 showed mixed astigmatism. The greatest amount of manifest hypermetropia found was +1·50 sphere and of myopia −5·50 sphere. The strongest minus cylinder was −1·50 (no sphere). Among the hypermetropes I have no note of a cylinder exceeding +·75.

The Use of the Eyes in Shooting.

In shooting two points have to be observed and aligned—viz., the mark and the foresight. In old days one would have added a third, the backsight. Nowadays the aperture sight has made this an automatic part of the alignment, and incidentally has increased the ease and rapidity of aim and shooting to a very great extent. It has also aided those with defective vision by diminishing the cone of rays. The average size of aperture used is 0·05 in. to 0·08 in., or even in some cases 0·1 in.

The majority of shooting men at the moment of firing focus the tip of the foresight, which, in the short service rifle, is approximately 32 in. from the eye. Before the final pressure is applied the attention is concentrated on maintaining the relative position of the point of aim and the tip of the foresight. I say point of aim advisedly, for some men take what is known as "a six o'clock" aim—i.e., the tip of the foresight just below the mark, others aim at the top of the target, and others at the bottom. The eye, therefore, while aiming is alternately relaxing and accommodating, finally settling for a fraction of a second in partial accommodation. It can, then, be readily understood that errors of refraction tend to cause fatigue in older shots, particularly on sunny days or when many shots are fired consecutively. Add to this the strain of using a telescope to mark the "spotting disc" and to judge the wind by the mirage and we see the main value of the correction of faulty refraction is not so much to *see* the object aimed at well, but to put the eye under the best conditions for hard use.

Correction of Visual Defects in Shooters.

In prescribing glasses the point to which I wish to draw attention is that an ordinarily centred lens is not advisable, because in the position assumed when firing the eye looks through the upper and inner quadrant of the lens. (The match rifle-shot who usually assumes the supine position is not in question, only the service rifle user.)

In the prone position the body is carried well away to the left, so that the head is inclined to the left also in the act of looking at the mark. The face is inclined at a more or less acute angle to the ground, and the right eye is slightly further from the target than the left (in a right-handed man). This necessitates the line of vision passing, as has been pointed out, through some point situated in the upper and inner quadrant of the right lens, and, if no alteration of centre is mentioned in the prescription, a prismatic and curved image is produced. To counteract this it is necessary (*a*) to raise the frame; (*b*) to centre the glass so that the line of aim and the optical centre coincide; (*c*) to bring the face of the glass parallel in the vertical plane with the target.

Theoretically the shooting glass should be angled to correspond in the horizontal plane also, but in practice this is hardly needed. It will be found that an angle of 10°–15° back from the vertical is required to fulfil (*c*). An angling joint can be used for this.

The question of the lens employed for the left eye is also of some importance. As most men shut the left eye while aiming, it might be thought that a monocle would be most convenient (with due provision for the correct axis of any cylinder used). Most men use the left eye for telescopic purposes, as mentioned above, and for this a normal centring is sufficient in a toric lens. Seeing, however, that whether the normal distance between the pupils is preserved in the centring, or whether the eyes are supposed to be used independently, the optical centres and the pupils will not correspond when the subject is walking about, it is as well to warn him to wear the glasses only when in the shooting position. With a strong minus lens the decentring causes the lower edge to be very broad, and it is as well either to order a lens smaller than usual in diameter or to cut away the lower half. With some types of aperture sight the latter is, in any case, an advantage, as the recoil sometimes brings part of the sight in contact with the base of the frame.

The glasses for big-game and game-bird shooting need not, I think, be brought under the above rules. Shots with the sporting rifle are not always taken in the prone position, and in any other position the eye is not rotated so much away from the centre of the frame; while the shot-gun user needs certainly to see his mark, but his alignment of the gun upon it is dependent very slightly on aim. Instinctive muscular control directs the barrels just as in revolver snap shooting. The proper fitting of a shot-gun to the individual's anatomical construction is nine-tenths of the making of a good game shot. In the military rifle no more than a certain alteration in the length of the stock is possible.

Much remains to be learned of the physiology of rifle shooting, both with regard to vision and psychology. The causes of bad shooting are legion, and it is not always easy to assign the proximate cause. On the whole I am inclined to think that vision is by no means the chief factor in the equipment of the great shot, but is only one of many.

first essential. He should be put to bed with as little disturbance as possible, his room kept quiet, and the light dim. His head and shoulders should be slightly raised on a pillow, care being taken that the large veins of his neck are not being pressed upon.

If the patient is conscious, visitors should be prohibited, and he must be protected from worries and physical exertion. He ought to be fed, and must not be allowed to alter his position in bed by his own exertions. A bedpan and urinal must be employed. If the patient is unconscious he should lie on his side, preferably on a water-bed, and the nurse must see that his head does not drop forward. He may be incontinent, but if urine is retained catheterisation will be necessary and should be carried out with minimal disturbance of the patient. His skin must be cleansed with soap and water night and morning to prevent the development of bedsores, and for this purpose the nurse should use the palm of her hand. After carefully drying his skin with a rough towel, she should gently rub his back, shoulders, and buttocks with methylated spirit, and finally dust them over with boric powder. If the patient is in a restless, semi-conscious state sedatives are necessary and, provided that he can swallow, bromides or chloral, or both combined, are preferable. As a draught the following is satisfactory: Pot. brom., 20 gr.; chloral hydrate 12 gr.; aq. menth. pip. ad 1 oz. Morphia is a depressant of the respiratory centre, but in the circumstances under which it would be called for this is no deterrent to its use in moderate doses. For restlessness is not usually associated with deep coma or other signs of increased intracranial pressure sufficient to impede medullary function.

Feeding.—Whether the stroke is severe or slight it is safe and probably wise to starve the patient for the first 24 hours. If he is conscious and thirsty he should be allowed sips of water but not large quantities of fluid. If he is unconscious, care must be taken to keep his mouth clean by swabbing it out with a mild antiseptic or alkaline lotion. After the first day semi-fluid diet can be given if necessary in the form of nutrient enemata. If the patient is feeble and his heart's action is poor, alcohol and digitalis are often beneficial. Even in mild cases the diet for a few days should be light and then gradually increased. When it is clear that the cause of the stroke is rupture of a vessel it is generally considered to be good practice to promote free action of the bowels by calomel or croton oil ♏ i., followed by an enema. If the vascular lesion is clearly thrombotic, and especially if the heart's action is weak, purgatives should be avoided, but enemata and mild laxatives can be used.

Where there is good reason to believe that syphilis is the cause of the arterial disease, anti-syphilitic treatment should be early instituted. Since it is important to disturb the patient as little as possible, it is necessary carefully to choose the drug to be employed and the method of its administration. Mercury by intramuscular injection is perhaps preferable, although arsenical compounds such as glucarsenol or sulpharsenol can be given in small doses into the buttock at weekly intervals under strict aseptic conditions. As soon as the patient is able to swallow, pot. iod. gr. x. to gr. xx., thrice daily, should be given.

Are Surgical Measures Justifiable?—Many of the clinical phenomena resulting from cerebral vascular lesions are due to raised intracranial pressure from hæmorrhage and œdema or œdema alone. When coma is deep or increasing the question therefore arises whether or not active measures ought to be adopted to relieve the cerebral compression that otherwise may kill the patient. It is a question by no means easy to answer. If, in addition to profound coma, there is clear evidence of disturbance of medullary function, such as rising blood pressure associated with Cheyne-Stokes respiration and cyanosis, relief of intracranial pressure is certainly necessary, for otherwise the patient is likely to die. As to the best method to adopt, bleeding by phlebotomy at one time played a prominent part in the routine treatment of apoplexy, and if sufficiently heroic it will certainly lower the intracranial pressure. But nowadays it is rarely employed. This is not to be wondered at, for it has only a limited usefulness and under certain circumstances may be positively dangerous. Thus when the circulation through the medulla is already enfeebled from either cardiac weakness or compression it is likely quickly to lead to a fatal result. Even in cases of cerebral hæmorrhage in which the heart is acting forcibly, the blood pressure is high, and respiration is not embarrassed. Although withdrawal of blood is unlikely to be harmful, it is doubtful whether any real benefit will result from it. Venesection on the whole has little to commend it.

Withdrawal of spinal fluid by lumbar puncture is sometimes employed, but where the pressure within the skull is sufficiently great to affect the medulla it is not a safe procedure. The danger, of course, lies in the risk of herniation of the bulb through the foramen magnum. In less severe cases, however, in which signs of bulbar compression are absent, careful drainage of spinal fluid by lumbar puncture is relatively safe and often leads to rapid relief of the general cerebral symptoms.

A third available method of dealing with raised intracranial pressure is by cerebral decompression. It has been strongly advocated by Cushing for apoplexy from hæmorrhage, thrombosis, or embolism, not only as a means of saving life, but also, in less serious cases, to restrict the amount of residual disability by diminishing local destruction of tissue from pressure due to œdema or blood-clot. Our knowledge of the results of this method is insufficient for judging whether or not it should be employed to the extent that Cushing advises. But it would seem to be clearly indicated when the blood pressure is rising and Cheyne-Stokes respiration is present; in other words, when the patient's life is *endangered from impairment of medullary function.*

Period of Rest in Bed.—The question as to how long a patient who has had a stroke should be kept in bed can be answered only in general terms and in regard to cases uncomplicated by bronchitis, heart failure, &c. In all severe cases the patient should be kept in bed for at least a month after consciousness has been recovered and other acute symptoms have passed off. Even when the stroke has been slight rest in bed for from 10 to 14 days is advisable.

Preventive Measures.

The physician's duties do not end when the patient has recovered from the acute effects of the vascular lesion. Apart from the treatment of residual disabilities, such as hemiplegia, he ought to review his patient's mode of living in order to ascertain whether anything can be done to avoid a recurrence. Thrombosis and hæmorrhage are probably always associated with arterial disease which cannot be eradicated. But it is often possible to diminish his liability to vascular accidents. Thus when syphilis is the essential cause adequate treatment ought to be persistently carried out. Patients with arterial hypertension should avoid excesses in food and alcohol as well as in mental and physical exertion. Worry is the common lot, but such patients should, as far as possible, avoid situations that are likely to be disturbing. Their diet should be light. Meat soups, strong coffee, and heavy meals should be avoided, and a regular morning saline is beneficial.

Lastly, although any reasonable abstinence ought to be insisted upon, it should be remembered that it is easy by excessive zeal for rules and regulations to foster a spirit of hopelessness in patients with vascular disease and to make their lives more miserable than need be. In consequence their activities should not be restricted within too narrow limits.

VISION AND TARGET SHOOTING.

BY C. WYNN WIRGMAN, M.D. LOND., F.R.C.S. ENG., *T.D.*,

LATE OPHTHALMOLOGIST, 17TH GENERAL HOSPITAL.

THE sport of rifle-shooting is by no means so popular in the British Isles as in the Overseas Dominions. There are several reasons that may be suggested, but no doubt the principal one is that Government encouragement is lacking. In the Dominions, Government support is hearty, and in consequence many more enthusiastic rifle shots are to be found. Still, there are many here who are constant visitors to Bisley, and the "King's" winner is a person of some small consideration. I therefore venture to make a few observations on the subject of sight in rifle-shooting and the special requirements for shooting spectacles.

The Essentials of Marksmanship.

Attainment of a high standard of marksmanship results from a combination of physical qualities, to which must be added certain mental characteristics as well. The public believe that good eyesight is the one great factor, but in this they are not quite accurate. Ability to see the object aimed at is certainly necessary, but not perfect vision. Fatigue of the eye, I think, and not bad definition, is the main cause of the difficulty in scoring well for a number of consecutive shots, as required in present-day competitions. I have had the opportunity of examining the eyes of many of the Bisley competitors, and it is upon these observations that this note is based.

Many of the younger men, although not emmetropic, do not feel the need of glasses so much, because fatigue is not so easily felt in youth where the application is not constant and intense. In Bisley shooting there is an interval for rest between each shot, possibly as much as two to three minutes when three competitors are firing at the same time.

Visual Defects in Shooters.

I have prescribed spectacles for 38 men who have been, or are, really good shots. Of these I find 22 were hypermetropic, 15 needing spheres only, and 7 cylinders with or without an additional sphere; 10 were myopic, and all but one of these needed cylinders as well as spheres: 6 showed mixed astigmatism. The greatest amount of manifest hypermetropia found was +1·50 sphere and of myopia −5·50 sphere. The strongest minus cylinder was −1·50 (no sphere). Among the hypermetropes I have no note of a cylinder exceeding +·75.

The Use of the Eyes in Shooting.

In shooting two points have to be observed and aligned—viz., the mark and the foresight. In old days one would have added a third, the backsight. Nowadays the aperture sight has made this an automatic part of the alignment, and incidentally has increased the ease and rapidity of aim and shooting to a very great extent. It has also aided those with defective vision by diminishing the cone of rays. The average size of aperture used is 0·05 in. to 0·08 in., or even in some cases 0·1 in.

The majority of shooting men at the moment of firing focus the tip of the foresight, which, in the short service rifle, is approximately 32 in. from the eye. Before the final pressure is applied the attention is concentrated on maintaining the relative position of the point of aim and the tip of the foresight. I say point of aim advisedly, for some men take what is known as "a six o'clock" aim—i.e., the tip of the foresight just below the mark, others aim at the top of the target, and others at the bottom. The eye, therefore, while aiming is alternately relaxing and accommodating, finally settling for a fraction of a second in partial accommodation. It can, then, be readily understood that errors of refraction tend to cause fatigue in older shots, particularly on sunny days or when many shots are fired consecutively. Add to this the strain of using a telescope to mark the "spotting disc" and to judge the wind by the mirage and we see the main value of the correction of faulty refraction is not so much to *see* the object aimed at well, but to put the eye under the best conditions for hard use.

Correction of Visual Defects in Shooters.

In prescribing glasses the point to which I wish to draw attention is that an ordinarily centred lens is not advisable, because in the position assumed when firing the eye looks through the upper and inner quadrant of the lens. (The match rifle-shot who usually assumes the supine position is not in question, only the service rifle user.)

In the prone position the body is carried well away to the left, so that the head is inclined to the left also in the act of looking at the mark. The face is inclined at a more or less acute angle to the ground, and the right eye is slightly further from the target than the left (in a right-handed man). This necessitates the line of vision passing, as has been pointed out, through some point situated in the upper and inner quadrant of the right lens, and, if no alteration of centre is mentioned in the prescription, a prismatic and curved image is produced. To counteract this it is necessary (*a*) to raise the frame; (*b*) to centre the glass so that the line of aim and the optical centre coincide; (*c*) to bring the face of the glass parallel in the vertical plane with the target.

Theoretically the shooting glass should be angled to correspond in the horizontal plane also, but in practice this is hardly needed. It will be found that an angle of 10°–15° back from the vertical is required to fulfil (*c*). An angling joint can be used for this.

The question of the lens employed for the left eye is also of some importance. As most men shut the left eye while aiming, it might be thought that a monocle would be most convenient (with due provision for the correct axis of any cylinder used). Most men use the left eye for telescopic purposes, as mentioned above, and for this a normal centring is sufficient in a toric lens. Seeing, however, that whether the normal distance between the pupils is preserved in the centring, or whether the eyes are supposed to be used independently, the optical centres and the pupils will not correspond when the subject is walking about, it is as well to warn him to wear the glasses only when in the shooting position. With a strong minus lens the decentring causes the lower edge to be very broad, and it is as well either to order a lens smaller than usual in diameter or to cut away the lower half. With some types of aperture sight the latter is, in any case, an advantage, as the recoil sometimes brings part of the sight in contact with the base of the frame.

The glasses for big-game and game-bird shooting need not, I think, be brought under the above rules. Shots with the sporting rifle are not always taken in the prone position, and in any other position the eye is not rotated so much away from the centre of the frame; while the shot-gun user needs certainly to see his mark, but his alignment of the gun upon it is dependent very slightly on aim. Instinctive muscular control directs the barrels just as in revolver snap shooting. The proper fitting of a shot-gun to the individual's anatomical construction is nine-tenths of the making of a good game shot. In the military rifle no more than a certain alteration in the length of the stock is possible.

Much remains to be learned of the physiology of rifle shooting, both with regard to vision and psychology. The causes of bad shooting are legion, and it is not always easy to assign the proximate cause. On the whole I am inclined to think that vision is by no means the chief factor in the equipment of the great shot, but is only one of many.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS:

ANNUAL CONFERENCE.

(BY OUR OWN CORRESPONDENT.)

THE Tenth Annual Conference of this Association was held in London on July 3rd and 4th.

Visit to Burrow Hill Training Colony.

On the 3rd the delegates to the Conference proceeded to the Burrow Hill Training Colony, Frimley, Surrey, where, under the guidance of Sir Robert Philip, Dr. F. N. Kay Menzies, Dr. A. H. Macpherson, and the instructors at the colony, a tour of the grounds and buildings was made. The institution is delightfully situated, with ample ground for cultivation. There are separate blocks for sanatorium purposes, housing of the trainees, administration, and kitchen. It was stated that, up to December last, seven men out of nine discharged from the colony from the rural carpentry department had obtained employment, and 9 out of 31 from the gardens, a certain number being retained in the colony for its needs. To the inquiry made by one of the delegates as to whether or not 12 months' residence was sufficient for the necessary training, came the reply that this depended largely on the man's initiative. All produce grown is credited to the department concerned, and it was stated that the farm had become self-supporting in the space of two years.

There are two sections of the colony—the sanatorium and the training. These appear to be independent of each other, the financial responsibility for the maintenance of the patients in the former being borne by the county authority sending the patients, and in the latter as to three-fourths by the Ministry of Pensions, and as to one-fourth by the National Association for the Prevention of Tuberculosis. The entire cost of the patient per week is £2 6*s.* 10¾*d.* in the sanatorium and £2 12*s.* 6¾*d.* in the training section. The diet, judging from the details given, seemed adequate and varied. A point to which attention was drawn was that in the colony there was unfortunately no coöperation between the two sections, the nominees for each coming through different and independent authorities. The great difficulty in the work, to which also Sir Robert Philip drew attention, is the lack of any machinery for finding employment for the trainee on completion of his training, and in regard to this he pointed out that responsibility rests not alone on the colony, but must be shared by the authority which sends the patient. Success could only come by whole-hearted coöperation between the colony and care associations, and by the movement becoming a national one.

On Friday, the 4th, the Association met at 10.30 A.M. in the Robert Barnes Hall of the Royal Society of Medicine. Sir Arthur Stanley, chairman of the council, occupied the chair, introduced Mr. Wheatley, Minister of Health, and welcomed representatives from the Dominions, France, Holland, and the U.S.A.

The Need for Care Committees.

Mr. Wheatley said that the Conference was engaged in a work on which he himself had spent many years. The fight against tuberculosis was a winning fight, however prolonged. In 1847 there were 3189 deaths from tuberculosis per 1,000,000 living; in 1861, 2675; in 1881, 1923; in 1901, 1263; and in 1921, 854. There had been not only steady but even rapid progress, but still we had 70,000 fresh notifications of tuberculosis every year. The decline in the death-rate, he said, was closely related to improvement in social conditions, and the fall began seriously when food supplies cheapened, side by side with the improvement in general sanitary conditions which marked the latter part of the nineteenth century, and the rate of progress would be measured by the rapidity with which proverty was eliminated. Doubt, he said, had been thrown on the value of sanatorium treatment, but he thought it had proved its value in two ways—first of all, by educating the patient in the rules of health, and, again, by prolonging his life. The great problem, however, is to know what to do with the patient when he leaves the sanatorium. Only too often he had to return to the social conditions—the old hell—which he was unable to withstand when he contracted the disease, a most discouraging fact, after the expenditure of so much money and care, and one giving cause for grave concern to a Minister of Health. There was no hope of the patient being able to compete in the industrial market with the physically fit, especially in periods of great unemployment. So, just when he required additional means for additional sustenance, he was deprived even of an ordinary standard of living. Since 1919 the Ministry of Health had been impressed with the necessity of establishing care committees. Local authorities should at once organise and supervise care committees, and should establish a close, friendly, and confidential coöperation between them and the patients. The patient must be approached on terms, not of social, but of human equality. Part of their work would be to emphasise the value of good personal habits. There remained the much greater problem of how the patients were to earn the necessaries of life, for merely to maintain the patient was not good for him. In the effort to select some particular forms of work which these people could do economically, with a measure of State and voluntary help, certain experiments had been carried out—village settlements, for example—but caution was necessary in these matters. Hundreds of thousands of tuberculous people had to be provided for. Was it not possible to provide some scheme of workshops where the patient could work under favourable conditions and return to a decent home at night? The great difficulty was that of finance, and six months of experience had taught him that the Treasury remained quite independent of any political conditions.

Mr. Wheatley concluded by asking the delegates to furnish him with practical suggestions and schemes which could be made applicable to the whole country, and so help him to smooth the path of the sufferers.

Dr. F. N. Kay Menzies then read his paper on the

Part Played by Training Colonies in the Treatment of Tuberculosis,

abstracted on p. 99 of this issue of THE LANCET.

In the discussion which followed the reading of the paper, Dr. A. Sandison (Ministry of Pensions) defined the position of the Ministry, which was to carry out the obligations imposed by Parliament with reference to ex-Service men and endeavour to effect their physical restoration; also without attempting to duplicate existing organisations, to supplement the gaps in local schemes by making financial provision for the family while the patient is undergoing treatment, and, in coöperation with the Ministry of Labour, to subsidise schemes of training.

Dr. Lissant Cox (Lancashire) said that the fact that only 7 men out of 50 sent from his area, with a population of 1,750,000, to outside colonies completed their course of training was another nail in the coffin of these schemes. He thought it might be wise to merge these institutions in a sanatorium, having for its object purposeful work without the present ridiculous limitations in the time of residence. As to the village settlement, he considered Papworth, of which alone he had knowledge, a brilliant success.

Dr. Peyton (Cheshire) said the results of treatment were disappointing, while restoration to working capacity was a varying quantity which could not be guaranteed, and it was wrong to place on modern industry the incubus of tuberculous labour since, even without overhead charges, it was impossible to make consumptive labour self-supporting.

Dr. N. D. Bardswell (London) thought vocational training valuable, not so much as a means of subsequent livelihood as of rendering an otherwise tedious treatment of sufficient interest to persuade men to remain in an institution a long time. In his opinion an industrial settlement has a greater chance of success if guided by enthusiastic voluntary effort than if fettered by the restrictions which public ownership necessarily entails.

Dr. Hefting (Minister for Labour for Holland) said that they had just begun in that country, and looked to England, for example, where he had seen much that would be useful to his own country.

Mr. Allen (Leeds) thought that settlements were the best method of dealing with the problem, although the cost rendered them impracticable. Concurrent treatment and training had little practical value, because there are certain parts of farm work which the tuberculous cannot and ought not to do. Leeds had established successful coöperation between medicine and the business world.

Mr. Thompson (Hastings and St. Leonards) stated that in his area out of nine trained men four were satisfactorily employed either at Preston Hall or at Hastings Infirmary, whilst it has been impossible to find employers of labour to take the others on.

At the afternoon meeting of Friday the Organisation of Care Committees was considered, upon an excellent paper from Lieut.-Colonel J. A. Ellis, B.Sc.

DIETARIES IN MENTAL HOSPITALS.

REPORT OF BOARD OF CONTROL COMMITTEE.

ON March 26th, 1922, a committee was appointed by Sir Frederick Willis, chairman of the Board of Control, to consider the dietaries in county and borough mental hospitals, and to report what changes, if any, are desirable, and whether a minimum dietary scale should be fixed. Dr. R. W. Branthwaite was appointed chairman, and Mr. Harold J. Clarke secretary of the committee, the other members being Dr. L. O. Fuller, medical superintendent of the Three Counties Mental Hospital, Arlesey; Mr. W. J. Gibbs, steward of the Tooting Bec Mental Hospital; Dr. Major Greenwood, a medical officer of the Ministry of Health; Dr. P. T. Hughes, medical superintendent of the Barnsley Hall Mental Hospital, Bromsgrove; and Dr. R. Worth, medical superintendent of the Springfield Mental Hospital, Tooting. The report is divided into six main sections:—

(1) Details concerning existing mental hospital dietaries; (2) the dietetic needs of the insane; (3) the model dietary; (4) administrative improvements in kitchen control and equipment necessary to carry out the model dietary; (5) the cost of the adoption of the model dietary; (6) conclusions and recommendations.

Appendices include (*a*) an analysis of mental hospital dietaries; (*b*) anthropometric data concerning the insane (by Dr. Major Greenwood); (*c*) a report on the rate of basal metabolism in the insane (by Dr. C. Gerald Ainsworth); (*d*) specimen forms of tender for purchase of meat, fish, and cocoa; (*e*) specification and drawings of a plate-warmer in use at Winwick Mental Hospital (by Mr. W. H. Houghton, A.M.I.M.E.); (*f*) the model dietary; (*g*) report on some matters concerning kitchen equipment in Canadian and American mental hospitals (by Mr. S. J. Benham); (*h*) the estimated cost at each mental hospital of the model dietary as originally circulated, with analysis.

The first section on

Existing Mental Hospital Dietaries

is founded mainly on conditions existing in 1922. It is noted that some improvement has since been made in the feeding arrangements at a few institutions. This section is subdivided into the following chapters:—

(1) The physiological sufficiency of mental hospital dietaries; (2) accessory food factors (vitamins) and mental hospital dietaries; (3) existing methods for the supply, preparation, cooking, and distribution of food; (4) conclusions concerning existing dietaries.

In this last chapter the conclusions reached are summarised as follows:—

1. That there is an undesirable inequality in the construction of dietary scales throughout mental hospitals, some being well balanced and thoughtfully designed, whilst others impressed us as lacking in ingenuity.

2. That an unsatisfactory irregularity exists in the quantities of some staple articles of food supplied; a bare majority of diets being approximately correct in this particular—i.e., supplying an average quantity—whilst the remainder were either obviously deficient or possibly excessive.

3. That insufficient attention is paid to palatability and attractiveness, especially in the matter of the provision of a reasonable variety of dishes; breakfasts and teas providing the most common evidence of this defect.

4. That, although the details with which we were provided did not enable us to construct an absolutely reliable arithmetical estimate of the value of each diet scale (in terms of proteins, fats, carbohydrates, and calories), the result of analysis proved useful as confirmatory evidence, in cases where other indications suggested inadequacy or excess.

5. That it proved especially difficult for us to ignore the great difference that exists between dietaries showing the lowest and highest caloric values respectively; justifying a suspicion that the supply of food in the former is insufficient. This conclusion received support from the increased incidence of tuberculosis amongst males in the 12 institutions providing dietaries of the lowest arithmetical value.

6. That there seems to be some ground for suggesting that mental hospital dietaries may be deficient in certain accessory food factors (vitamins); probably deficient in fat-soluble A, and possibly also in water-soluble B.

7. That, when markets are available, some modification in the usual methods adopted for obtaining supplies is desirable, with a view to securing a greater variety of meat foods, with due regard to economy.

8. That every effort should be made to maintain a sufficient supply of high grade milk, the daily amount provided being inadequate in some mental hospitals and unduly restricted in others, and that, in order to secure good quality, especially in the matter of fat-content, routine analysis is essential.

9. That there are grounds for the suggestion that the complete substitution of margarine for butter has eliminated one of the most valuable sources for the supply of fat-soluble A, and that the partial reinstatement of butter is desirable.

10. That some institution dietaries would be improved by the more frequent and regular supply of fresh (especially green) vegetables, and fruit, and that, in order to carry this into effect, the close coördination that exists in many institutions between the farm management and the person responsible for kitchen supply should be universal.

11. That, although some mental hospital kitchens have been kept up-to-date, there are still many that are so inadequately equipped as to be incapable of anything more than the simplest routine cookery, whilst there are a large number that would be capable of still better work if provided with improved facilities.

12. That there is need for greater attention, in many institutions, to kitchen organisation, methods of transport, and ward equipment, in order that the supply of hot food to patients may be secured.

13. That there is reason to believe that smooth working, efficiency, and economy would result from the placing of all duties relating to the supply, preparation, and distribution of food, under the supervision of one individual, who should be responsible for their proper execution.

The Dietetic Needs of the Insane.

As to the dietetic needs of the insane, the committee conclude that the bases set out in the Report on the Food Requirements of Man, by the Food (War) Committee of the Royal Society,[1] are as applicable to patients in mental hospitals as they are to the general population, with certain modifications[2]; that the figures of body surface, used in that report for the computation of minimum energy requirements, should be adopted as applying with equal force to the insane population; that it is necessary to allow for patients in mental hospitals, as did the Royal Society's

---

[1] Harrison and Sons, March, 1919.

[2] The only modifications considered necessary are the substitution of 11 for 8 hours' sleep and the estimation of an average "work" allowance of 400 calories net energy for both sexes, or about one-third more than the Royal Society's Committee estimated for a tailor. The chief consideration that led to the adoption of the latter modification was the fact that, although only a comparatively small proportion do really hard work on farms or in gardens, kitchens, laundries, &c., others not so employed are expending energy for a fair part of each day in ward work, if only "pottering about," in restless or aimless movement in wards or airing courts, or in muscular exercise accompanying even moderate excitement or mental irritability. All such patients expend more energy during the course of a day than does a tailor at his occupation.

Committee for the general population, a 10 per cent. increase to represent the difference between food as purchased and food digested, and a further addition applicable even in the most sedentary occupations of 300 calories per diem for "locomotion"; that upon the grounds detailed in the foregoing paragraphs the net energy requirements of male and female patients in mental hospitals, in terms of calorie values, may be calculated at approximately 2800 for males and 2500 for females. These figures should be regarded as standard minimum figures applicable to the ordinary population of mental hospitals, and there should be an addition of suitable energy values in the case of individual patients who are really actively employed.

The Model Dietary.

It was obvious that any attempt to impose a hard-and-fast standard dietary, for use in all mental hospitals, would be doomed to failure. Patients vary in type in different institutions, which, again, are conducted under widely different conditions. Moreover, it was considered important that nothing should be done to tie the hands of managing authorities to such an extent as to cripple enterprise or interfere with the exercise of ingenuity. It is emphasised in the report that the scale suggested for winter months is not to be regarded in any sense as a fixed dietary for universal use, but merely to serve as a model for the guidance of visiting committees, to show what are regarded as the food requirements for ordinary patients in a mental hospital, and to demonstrate the possibility of providing a dietary, in which a reasonable variety is maintained, at a moderate cost.

A Model Dietary (Abridged) for Adult Patients During Winter Months.

Breakfast (daily).—Males, 6 oz. bread; females, 5 oz. bread; tea, coffee, or cocoa, 1 pint; margarine or butter, ½ oz. With one or other of the following extras: Galantine of beef, brawn (beef or pork), veal loaf, breakfast sausage, corned beef, bacon, rissoles, black puddings, fish cakes, kedjeree, kipper, bloater, haddock, egg, marmalade, jam, cheese, macaroni cheese, or porridge. The allowance for each patient, on alternate days with ½ pint porridge, is 2 oz. of any of the above-mentioned prepared meats, 4 oz. dried fish, or 1 oz. cheese or jam. Butter should be mixed with margarine in the proportion of 25 per cent. of the former to 75 per cent. of the latter, or be given (½ oz.) in place of margarine at seven breakfasts or teas (at least) during each two weeks. From April to September stewed fruit, marmalade, jam, &c., may replace porridge. In no case should breakfast consist of a beverage and bread and margarine (or butter) only.

Dinners (October–March).—The allowances are as follows:—

	Males.	Females.
Meat, uncooked, and including bone	6 oz.	5 oz.
Bacon, boiled, ditto	3 ,,	2½,,
Fish (including bone-cleaned, ready for cooking)	8 ,,	7 ,,
Rabbit or meat pie or pudding	20 ,,	17 ,,
Soups	1 pint	1 pint
Stews	1 ,,	1 ,,
Potatoes (unpeeled and uncooked)—		
Only with fish	9 oz.	7 oz.
In addition to fresh vegetables with roast or boiled meat dinner	7 ,,	6 ,,
With stew	8 ,,	8 ,,
Fresh vegetables—i.e., greens, carrots, parsnips, turnips, onions, &c.	6 ,,	6 ,,
Bread	2 ,,	2 ,,
Puddings (flour), such as jam, treacle, raisin, currant, date, fig, ginger, bread, &c.	8 ,,	8 ,,
Puddings (milk)—rice, sago, tapioca, semolina	½ pint	½ pint
Bread and cheese—		
Bread	2 oz.	2 oz.
Cheese	1½,,	1½,,

Alternative dinner dishes are hot pot, cottage pie, shepherd's pie, sea pie, liver and bacon, pork and beans, sausages, curried meat or rabbit, haricot ox tails, tripe and onions, &c. An apple, orange, or banana should be given for dessert (or at tea) at least twice a week throughout the winter months.

During the summer some of the hot dinners should be replaced by cold, accompanied by salads, lettuces, radishes, tomatoes, &c., and fresh fruit puddings or stewed fruit substituted for some of the heavier suet puddings; fresh uncooked fruit should be regularly supplied when obtainable at reasonable cost.

Tea (October–March) (daily).—Males, 5 oz. bread; females, 3 oz. bread; cake, 3 oz.; margarine or butter, ½ oz.; tea, cocoa, or coffee, 1 pint. With one or other of the following extras: Jam or marmalade, seven times per fortnight, 1 oz. each patient; meat or fish paste, bloater, or shrimp and salmon, &c., seven times per fortnight, ½ oz. each patient.

The supply of cake should be varied, being made either with currants, sultanas, raisins, or carraway seeds. Scones, buns, or oatmeal biscuits of the same weight may be issued in lieu. During summer months the jam or pastes should be replaced by fresh vegetables or fruit. Lettuces, onions, tomatoes, radishes, watercress, mustard and cress, or beetroot are desirable foods, for the regular provision of which arrangements should be made.

There follow tables showing a sequence of dinner meals for male and female patients, respectively, covering a period of four weeks, designed to demonstrate the amount and kind of food that, in the opinion of the committee should be provided for this particular meal in order to secure sufficiency and variety. It is suggested that the order of these meals should be changed at the end of each four weeks, so that no particular dish can become associated with any particular day.

A typical week's menu is:—Sunday: Roast beef, potatoes, greens, milk pudding. Monday: Lentil soup, golden pudding. Tuesday: Rabbit pie, greens. Wednesday: Boiled mutton, potatoes, onions, jam roll pudding. Thursday: Meat stew, potatoes, dumplings. Friday: Fried hake, potatoes, raisin pudding. Saturday: Meat puddings, greens.

The total issues of this week's dietary in pounds per week for 100 male patients and for 100 female patients are set out below:—

Foodstuff.	Males.	Females.	Foodstuff.	Males.	Females.
	lb.	lb.		lb.	lb.
Beef	$93\frac{3}{4}$	$82\frac{13}{16}$	Sago	$3\frac{1}{8}$	$3\frac{1}{8}$
Mutton	$37\frac{1}{2}$	$31\frac{1}{4}$	Rice, tapioca, sago, semolina.	$6\frac{1}{4}$	$6\frac{1}{4}$
Rabbits	$37\frac{1}{2}$	$31\frac{7}{8}$	Baking powder	$\frac{15}{16}$	$\frac{15}{16}$
Fish (hake)	50	$43\frac{3}{4}$	Golden syrup and jam	$12\frac{1}{2}$	$12\frac{1}{2}$
Potatoes	$293\frac{3}{4}$	$253\frac{3}{4}$	Sugar	$6\frac{1}{4}$	$6\frac{1}{4}$
Greens	$112\frac{1}{2}$*	150*	Raisins	$6\frac{1}{4}$	$6\frac{1}{4}$
Other vegetables	$121\frac{14}{16}$	$81\frac{5}{8}$	Bread	$110\frac{15}{16}$	$110\frac{15}{16}$
Suet	33	$31\frac{1}{8}$	Milk	50 pints.	50 pints.
Flour	$98\frac{1}{16}$	$90\frac{9}{16}$			
Barley	$3\frac{1}{8}$	$3\frac{1}{8}$			
Lentils	$6\frac{1}{4}$	$6\frac{1}{4}$			
Split peas	$3\frac{1}{8}$	$3\frac{1}{8}$			

* It is not easy to understand why 100 female patients should be held to require 37½ lb. more greens during the week than 100 male patients. The greens are presumably given mainly to provide bulk and vitamins and can hardly be intended to replace the extra supply of protein foods suggested in the male dietary.—ED. L.

Details of ingredients for all the dishes suggested are appended, even to the amount of tea, sugar, and milk to be used for 100 pints.

The extreme variation in the expenditure of energy by patients rendered the construction of a model dietary, scientifically adjusted to suit the requirements of all patients in mental hospitals, an impossible task. The committee decided to regard all inmates of mental hospitals as falling within one or other of two categories: (*a*) the physically fit, or approximately fit, whether workers or non-workers, and (*b*) the infirm and sick. On this basis the model dietary should apply to nearly 75 per cent. of all patients in mental hospitals. In some of the dietary scales in current use supplied to the committee the evidence seemed to point to the diet of non-workers being barely sufficient, whilst that for workers had in general the appearance of being generous; a condition doubtless designed to encourage work, for therapeutic and economic reasons. Whilst the committee are in full agreement with the exercise of all reasonable efforts to induce patients to occupy themselves for their own advantage and that of the community, they are not satisfied that reliance upon additional food to produce this result is altogether justifiable. Many of the unemployed are physically unfit for regular work and need a good dietary for therapeutic reasons, and many are non-workers because of mental disease, although physically fit. They think that if the full dietary is extended to non-workers also, so far as it reasonably can be, the incidence of diseases such as tuberculosis and dysentery will be proportionately diminished. The establishment of a token system and the provision of facilities for the purchase of luxuries may be used to provide the necessary stimulus to effort among those who can work.

A Minimum Dietary.

The committee are of opinion that no dietary for ordinary patients in any mental hospital (including both workers and non-workers, and excluding the infirm and sick) should be allowed to fall below the nutritive and calorie values of the model, and that no dietary should be less varied in character than is indicated in their model scales. The dietetic requirements of the infirm and sick are matters that must be left to the discretion of the medical staff, and the substituted dietaries proposed for the infirm are therefore merely tentative suggestions.

The fourth section of the report is devoted to the administrative improvements necessary to carry out the model dietary, the chief of which appears to be the delegation of responsibility for the supply, cooking, and distribution, and service of food to one person. The committee advocate, in order to secure a better food supply and greater economy, a general improvement in the status of stewards, and the gradual conversion of the holder of this post from one who is now little more than a machine into an administrator with responsibility, and proportionately increased remuneration. They do not suggest, however, the wholesale transformation of existing stewards into food controllers because they happen now to be stewards, or any general disturbance of existing conditions in order to bring such a scheme into force immediately. The development must of necessity be a gradual one. As to the kitchen, this should be controlled, under the guidance of the person who is responsible for general direction, by one who is willing to abandon old routine methods, adopt new ones, and show readiness to exercise ingenuity in the production of a dietary at the lowest cost compatible with a good and varied scale. Great care should be exercised in the choice of the head of the kitchen staff; the committee recommend the abolition of the designation "cook" as denoting more a domestic servant than a responsible officer, with the substitution therefore of "kitchen superintendent" or "kitchen supervisor." Such a scheme would, no doubt, necessitate a higher rate of remuneration, but this is indicated in any case in many hospitals, and should be made dependent upon efficient administration. As to kitchen equipment, a list is given of items of equipment of proved value only, all of which are useful adjuncts from an economic standpoint.

Cost of the Adoption of the Model Dietary.

Unfortunately a comparison between present expenditure on food in mental hospitals and the cost of the adoption of the model scale was not easy to make, as so many mental hospital authorities are unable to produce details concerning food supplied to their patients as distinct from that provided for staff. The committee strongly urge the desirability of separate accounting in future, as is done in establishments under the control of the Metropolitan Asylums Board. In the absence of separate data it is difficult to decide whether an institution is conducted with due regard to economy or not, and, if not, where the fault is to be found. When food expenditure for staff and patients is grouped under one heading, the total cost of the two may not call for comment; whereas, if dissected, it may be found that the outlay on patients' account is unreasonably low, and that for staff unnecessarily high. In order to obtain some definite data on which to base an estimate of the cost of the suggested model dietary, copies were circulated to medical superintendents of 95 mental hospitals, accompanied by a schedule containing the exact quantities of all articles for an average week for 100 patients, 50 of each sex. The discrepancy between the replies received is astonishing. In one mental hospital (Plymouth) the total cost of the provisions is £33 17*s*. 10*d*., with a range of values at other places down to the lowest (Lancaster) £18 2*s*. 2*d*. Extremes of estimated cost are conspicuous under every item of expenditure—due, in part, to lack of uniformity in methods of purchase, to variety in character of material obtained, or to the accessibility or inaccessibility of markets, but in the main, it is thought, to the absence of any proper principle governing the charging up of home produce at regulated prices.

In commenting on the variations in the returns as to meat, potatoes, and vegetables, it is pointed out that the prices charged for articles supplied from home farms should represent current local market figures. It is probable that in many instances prices are unduly inflated in order to show a profit on farm management. For example, the main supply of milk is obtained from hospital farms, but the price at which it is invoiced to institutions varies from 9*d*. to 2*s*. 6*d*. per gallon, a difference in cost that can hardly be justified. The cost of the model dietary according to the average of the estimates from 95 institutions would work out at 8·2*d*. per head per day, and should not in the considered opinion of the committee exceed 8·5*d*. in county and 8·75*d*. in borough institutions. Whether or no these figures exceed existing expenditure on food in the majority of hospitals, the committee are of opinion that no local authority can consider the amounts as other than economically justifiable.

The report ends with the following

Conclusions and Recommendations.

1. That there should be more uniformity in the construction of mental hospital dietary scales, especially in regard to (*a*) the character of food given; (*b*) its total amount; (*c*) the amounts of certain staple articles of diet; and (*d*) the avoidance of monotony.

2. That the average calorie values of dietaries for ordinary patients in mental hospitals (including workers, and excluding those on substituted diets) should not fall below 3220 for males, and 2875 for females.

3. That to ensure the presence in dietaries of necessary accessory food factors (vitamins) there should be a partial reinstatement of butter as a regular article of diet, a supply of milk in greater quantity, an increased provision of green and other fresh vegetables, a more common use of eggs, a free administration of salads and fresh fruit, and a more general use of wholemeal or germ bread.

4. That, as these improvements would be secured by the adoption of our suggested model dietary, and as, under proper conditions, the cost of this dietary at present prices should not exceed 8½*d*. per head per day for county mental hospitals, and 8¾*d*. for borough institutions, we commend its general adoption in public mental hospitals, with such modifications as may be necessary to meet varying local conditions.

5. On grounds of economy as well as efficiency it is important: (*a*) To establish a unified food department in each institution, under a competent and responsible head, for dealing with the supply, cooking, distribution, and service of food; (*b*) to provide each institution with adequate kitchen equipment; (*c*) to endeavour to secure, as kitchen workers, the services of persons more highly skilled in cookery by making these posts more remunerative and attractive. This refers more particularly to the responsible head; and (*d*) to pay greater attention in many hospitals to other points dealt with in the body of this report relating to the cooking, distribution, and service of food.

6. That substantial economies can be secured by paying greater attention to the terms of specifications and contracts, and by taking more advantage of wholesale markets.

7. That, in regard to food expenditure, separate accounting, as between patients and staff, should be the rule in all mental hospitals.

8. That it would be a great advantage if an officer skilled in these details could be appointed on the Board of Control staff temporarily, to advise and assist local authorities in regard to the adoption of the model dietary.

The committee desire to acknowledge the marked ability with which Mr. Harold J. Clarke has discharged his duties as secretary.

Committee for the general population, a 10 per cent. increase to represent the difference between food as purchased and food digested, and a further addition applicable even in the most sedentary occupations of 300 calories per diem for "locomotion"; that upon the grounds detailed in the foregoing paragraphs the net energy requirements of male and female patients in mental hospitals, in terms of calorie values, may be calculated at approximately 2800 for males and 2500 for females. These figures should be regarded as standard minimum figures applicable to the ordinary population of mental hospitals, and there should be an addition of suitable energy values in the case of individual patients who are really actively employed.

The Model Dietary.

It was obvious that any attempt to impose a hard-and-fast standard dietary, for use in all mental hospitals, would be doomed to failure. Patients vary in type in different institutions, which, again, are conducted under widely different conditions. Moreover, it was considered important that nothing should be done to tie the hands of managing authorities to such an extent as to cripple enterprise or interfere with the exercise of ingenuity. It is emphasised in the report that the scale suggested for winter months is not to be regarded in any sense as a fixed dietary for universal use, but merely to serve as a model for the guidance of visiting committees, to show what are regarded as the food requirements for ordinary patients in a mental hospital, and to demonstrate the possibility of providing a dietary, in which a reasonable variety is maintained, at a moderate cost.

A Model Dietary (Abridged) for Adult Patients During Winter Months.

Breakfast (daily).—Males, 6 oz. bread; females, 5 oz. bread; tea, coffee, or cocoa, 1 pint; margarine or butter, ½ oz. With one or other of the following extras: Galantine of beef, brawn (beef or pork), veal loaf, breakfast sausage, corned beef, bacon, rissoles, black puddings, fish cakes, kedjeree, kipper, bloater, haddock, egg, marmalade, jam, cheese, macaroni cheese, or porridge. The allowance for each patient, on alternate days with ½ pint porridge, is 2 oz. of any of the above-mentioned prepared meats, 4 oz. dried fish, or 1 oz. cheese or jam. Butter should be mixed with margarine in the proportion of 25 per cent. of the former to 75 per cent. of the latter, or be given (½ oz.) in place of margarine at seven breakfasts or teas (at least) during each two weeks. *From April to September* stewed fruit, marmalade, jam, &c., may replace porridge. In no case should breakfast consist of a beverage and bread and margarine (or butter) only.

Dinners (October–March).—The allowances are as follows:—

	Males.		Females.
Meat, uncooked, and including bone ..	6 oz.	..	5 oz.
Bacon, boiled, ditto	3 ,,	..	2½,,
Fish (including bone-cleaned, ready for cooking)	8 ,,	..	7 ,,
Rabbit or meat pie or pudding	20 ,,	..	17 ,,
Soups	1 pint	..	1 pint
Stews	1 ,,	..	1 ,,
Potatoes (unpeeled and uncooked)—			
Only with fish	9 oz.	..	7 oz.
In addition to fresh vegetables with roast or boiled meat dinner	7 ,,	..	6 ,,
With stew	8 ,,	..	8 ,,
Fresh vegetables—i.e., greens, carrots, parsnips, turnips, onions, &c.	6 ,,	..	6 ,,
Bread	2 ,,	..	2 ,,
Puddings (flour), such as jam, treacle, raisin, currant, date, fig, ginger, bread, &c.	8 ,,	..	8 ,,
Puddings (milk)—rice, sago, tapioca, semolina	½ pint	..	½ pint
Bread and cheese—			
Bread	2 oz.	..	2 oz.
Cheese	1½,,	..	1½,,

Alternative dinner dishes are hot pot, cottage pie, shepherd's pie, sea pie, liver and bacon, pork and beans, sausages, curried meat or rabbit, haricot ox tails, tripe and onions, &c. An apple, orange, or banana should be given for dessert (or at tea) at least twice a week throughout the winter months.

During the summer some of the hot dinners should be replaced by cold, accompanied by salads, lettuces, radishes, tomatoes, &c., and fresh fruit puddings or stewed fruit substituted for some of the heavier suet puddings; fresh uncooked fruit should be regularly supplied when obtainable at reasonable cost.

Tea (October–March) (daily).—Males, 5 oz. bread; females, 3 oz. bread; cake, 3 oz.; margarine or butter, ½ oz.; tea, cocoa, or coffee, 1 pint. With one or other of the following extras: Jam or marmalade, seven times per fortnight, 1 oz. each patient; meat or fish paste, bloater, or shrimp and salmon, &c., seven times per fortnight, ½ oz. each patient.

The supply of cake should be varied, being made either with currants, sultanas, raisins, or carraway seeds. Scones, buns, or oatmeal biscuits of the same weight may be issued in lieu. During summer months the jam or pastes should be replaced by fresh vegetables or fruit. Lettuces, onions, tomatoes, radishes, watercress, mustard and cress, or beetroot are desirable foods, for the regular provision of which arrangements should be made.

There follow tables showing a sequence of dinner meals for male and female patients, respectively, covering a period of four weeks, designed to demonstrate the amount and kind of food that, in the opinion of the committee should be provided for this particular meal in order to secure sufficiency and variety. It is suggested that the order of these meals should be changed at the end of each four weeks, so that no particular dish can become associated with any particular day.

A typical week's menu is:—Sunday: Roast beef, potatoes, greens, milk pudding. Monday: Lentil soup, golden pudding. Tuesday: Rabbit pie, greens. Wednesday: Boiled mutton, potatoes, onions, jam roll pudding. Thursday: Meat stew, potatoes, dumplings. Friday: Fried hake, potatoes, raisin pudding. Saturday: Meat puddings, greens.

The total issues of this week's dietary in pounds per week for 100 male patients and for 100 female patients are set out below:—

Foodstuff.	Males.	Females.	Foodstuff.	Males.	Females.
	lb.	lb.		lb.	lb.
Beef.. ..	$93^{3}/_{4}$	$82^{13}/_{16}$	Sago ..	$3^{1}/_{8}$	$3^{1}/_{8}$
Mutton ..	$37^{1}/_{2}$	$31^{1}/_{4}$	Rice, tapioca, sago, semolina.	$6^{1}/_{4}$	$6^{1}/_{4}$
Rabbits ..	$37^{1}/_{2}$	$31^{7}/_{8}$	Baking powder	$^{15}/_{16}$	$^{11}/_{16}$
Fish (hake)	50	$43^{3}/_{4}$	Golden syrup and jam ..	$12^{1}/_{2}$	$12^{1}/_{2}$
Potatoes ..	$293^{3}/_{4}$	$253^{3}/_{4}$	Sugar....	$6^{1}/_{4}$	$6^{1}/_{4}$
Greens ..	$112^{1}/_{2}$*	150*	Raisins ..	$6^{1}/_{4}$	$6^{1}/_{4}$
Other vegetables	$121^{14}/_{16}$	$81^{5}/_{8}$	Bread ..	$110^{15}/_{16}$	$110^{15}/_{16}$
Suet.. ..	33	$31^{1}/_{8}$	*Milk* ..	*50 pints.*	*50 pints.*
Flour ..	$98^{1}/_{16}$	$90^{9}/_{16}$			
Barley ..	$3^{1}/_{8}$	$3^{1}/_{8}$			
Lentils ..	$6^{1}/_{4}$	$6^{1}/_{4}$			
Split peas .	$3^{1}/_{8}$	$3^{1}/_{8}$			

* It is not easy to understand why 100 female patients should be held to require 37½ lb. more greens during the week than 100 male patients. The greens are presumably given mainly to provide bulk and vitamins and can hardly be intended to replace the extra supply of protein foods suggested in the male dietary.—ED. L.

Details of ingredients for all the dishes suggested are appended, even to the amount of tea, sugar, and milk to be used for 100 pints.

The extreme variation in the expenditure of energy by patients rendered the construction of a model dietary, scientifically adjusted to suit the requirements of all patients in mental hospitals, an impossible task. The committee decided to regard all inmates of mental hospitals as falling within one or other of two categories: (*a*) the physically fit, or approximately fit, whether workers or non-workers, and (*b*) the infirm and sick. On this basis the model dietary should apply to nearly 75 per cent. of all patients in mental hospitals. In some of the dietary scales in current use supplied to the committee the evidence seemed to point to the diet of non-workers being barely sufficient, whilst that for workers had in general the appearance of being generous; a condition doubtless designed to encourage work, for therapeutic and economic reasons. Whilst the committee are in full agreement with the exercise of all reasonable efforts to induce patients to occupy themselves for their own advantage and that of the community, they are not satisfied that reliance upon additional food to produce this result is altogether justifiable. Many of the unemployed are physically unfit for regular work and need a good dietary for therapeutic reasons, and many are non-workers because of mental disease, although physically fit. They think that if the full dietary is extended to non-workers also, so far as it reasonably can be, the incidence of diseases such as tuberculosis and dysentery will be proportionately diminished. The establishment of a token system and the provision of facilities for the purchase of luxuries may be used to provide the necessary stimulus to effort among those who can work.

A Minimum Dietary.

The committee are of opinion that no dietary for ordinary patients in any mental hospital (including both workers and non-workers, and excluding the infirm and sick) should be allowed to fall below the nutritive and calorie values of the model, and that no dietary should be less varied in character than is indicated in their model scales. The dietetic requirements of the infirm and sick are matters that must be left to the discretion of the medical staff, and the substituted dietaries proposed for the infirm are therefore merely tentative suggestions.

The fourth section of the report is devoted to the administrative improvements necessary to carry out the model dietary, the chief of which appears to be the delegation of responsibility for the supply, cooking, and distribution, and service of food to one person. The committee advocate, in order to secure a better food supply and greater economy, a general improvement in the status of stewards, and the gradual conversion of the holder of this post from one who is now little more than a machine into an administrator with responsibility, and proportionately increased remuneration. They do not suggest, however, the wholesale transformation of existing stewards into food controllers because they happen now to be stewards, or any general disturbance of existing conditions in order to bring such a scheme into force immediately. The development must of necessity be a gradual one. As to the kitchen, this should be controlled, under the guidance of the person who is responsible for general direction, by one who is willing to abandon old routine methods, adopt new ones, and show readiness to exercise ingenuity in the production of a dietary at the lowest cost compatible with a good and varied scale. Great care should be exercised in the choice of the head of the kitchen staff; the committee recommend the abolition of the designation "cook" as denoting more a domestic servant than a responsible officer, with the substitution therefore of "kitchen superintendent" or "kitchen supervisor." Such a scheme would, no doubt, necessitate a higher rate of remuneration, but this is indicated in any case in many hospitals, and should be made dependent upon efficient administration. As to kitchen equipment, a list is given of items of equipment of proved value only, all of which are useful adjuncts from an economic standpoint.

Cost of the Adoption of the Model Dietary.

Unfortunately a comparison between present expenditure on food in mental hospitals and the cost of the adoption of the model scale was not easy to make, as so many mental hospital authorities are unable to produce details concerning food supplied to their patients as distinct from that provided for staff. The committee strongly urge the desirability of separate accounting in future, as is done in establishments under the control of the Metropolitan Asylums Board. In the absence of separate data it is difficult to decide whether an institution is conducted with due regard to economy or not, and, if not, where the fault is to be found. When food expenditure for staff and patients is grouped under one heading, the total cost of the two may not call for comment; whereas, if dissected, it may be found that the outlay on patients' account is unreasonably low, and that for staff unnecessarily high. In order to obtain some definite data on which to base an estimate of the cost of the suggested model dietary, copies were circulated to medical superintendents of 95 mental hospitals, accompanied by a schedule containing the exact quantities of all articles for an average week for 100 patients, 50 of each sex. The discrepancy between the replies received is astonishing. In one mental hospital (Plymouth) the total cost of the provisions is £33 17*s*. 10*d*., with a range of values at other places down to the lowest (Lancaster) £18 2*s*. 2*d*. Extremes of estimated cost are conspicuous under every item of expenditure—due, in part, to lack of uniformity in methods of purchase, to variety in character of material obtained, or to the accessibility or inaccessibility of markets, but in the main, it is thought, to the absence of any proper principle governing the charging up of home produce at regulated prices.

In commenting on the variations in the returns as to meat, potatoes, and vegetables, it is pointed out that the prices charged for articles supplied from home farms should represent current local market figures. It is probable that in many instances prices are unduly inflated in order to show a profit on farm management. For example, the main supply of milk is obtained from hospital farms, but the price at which it is invoiced to institutions varies from 9*d*. to 2*s*. 6*d*. per gallon, a difference in cost that can hardly be justified. The cost of the model dietary according to the average of the estimates from 95 institutions would work out at 8·2*d*. per head per day, and should not in the considered opinion of the committee exceed 8·5*d*. in county and 8·75*d*. in borough institutions. Whether or no these figures exceed existing expenditure on food in the majority of hospitals, the committee are of opinion that no local authority can consider the amounts as other than economically justifiable.

The report ends with the following

Conclusions and Recommendations.

1. That there should be more uniformity in the construction of mental hospital dietary scales, especially in regard to (*a*) the character of food given; (*b*) its total amount; (*c*) the amounts of certain staple articles of diet; and (*d*) the avoidance of monotony.

2. That the average calorie values of dietaries for ordinary patients in mental hospitals (including workers, and excluding those on substituted diets) should not fall below 3220 for males, and 2875 for females.

3. That to ensure the presence in dietaries of necessary accessory food factors (vitamins) there should be a partial reinstatement of butter as a regular article of diet, a supply of milk in greater quantity, an increased provision of green and other fresh vegetables, a more common use of eggs, a free administration of salads and fresh fruit, and a more general use of wholemeal or germ bread.

4. That, as these improvements would be secured by the adoption of our suggested model dietary, and as, under proper conditions, the cost of this dietary at present prices should not exceed 8½*d*. per head per day for county mental hospitals, and 8¾*d*. for borough institutions, we commend its general adoption in public mental hospitals, with such modifications as may be necessary to meet varying local conditions.

5. On grounds of economy as well as efficiency it is important: (*a*) To establish a unified food department in each institution, under a competent and responsible head, for dealing with the supply, cooking, distribution, and service of food; (*b*) to provide each institution with adequate kitchen equipment; (*c*) to endeavour to secure, as kitchen workers, the services of persons more highly skilled in cookery by making these posts more remunerative and attractive. 6. That substantial economies can be secured by paying greater attention to the terms of specifications and contracts, and by taking more advantage of wholesale markets.

7. That, in regard to food expenditure, separate accounting, as between patients and staff, should be the rule in all mental hospitals.

8. That it would be a great advantage if an officer skilled in these details could be appointed on the Board of Control staff temporarily, to advise and assist local authorities in regard to the adoption of the model dietary.

The committee desire to acknowledge the marked ability with which Mr. Harold J. Clarke has discharged his duties as secretary.

CONFERENCE ON INFANT WELFARE.

THE Third English-speaking Conference on Infant Welfare was opened by Mr. Wheatley, the Minister of Health, at Caxton Hall, Westminster, on July 1st, Dr. G. F. Still presiding. There were about 700 delegates present from 30 different countries.

Mr. Wheatley said that their object was not to relieve mothers, but to train and help them. No governing body could replace the mother. Maternal mortality from childbirth had not declined, and his department was giving great attention to this preventable mortality and the morbidity which was inevitably associated with it. A circular would shortly be issued to local authorities reminding them of their powers. The first essential was care of the expectant mother. By medical inspection in the schools the future mothers would be physically better; by the teaching of mothercraft they would be better equipped mentally. Three things were necessary: antenatal medical supervision, a more highly skilled obstetric service, and homes safe for confinements. Until better homes were obtained more lying-in hospitals and homes were needed. The number of lying-in homes aided by the Ministry was 135 and he hoped many more beds would soon be available. These lying-in homes had a great educational value. Infant mortality had been halved since 1900, and he believed the reduction was largely due to those engaged in child welfare work. There were still black spots in industrial districts and they must bring opportunity to those in need and not rest content until the worst wards of a town were as good as the best. In introducing a system for the care of expectant mothers they had to combat prejudice and conservatism. They needed a greater army of helpers and, if they were to succeed, the help given must not be tainted by charity or patronage. The workers engaged must get down to the same human, if not the same social level, as those to be helped. Health visitors needed a very thorough training. It was slower work training a health visitor than training a "dilutee" for building houses. The period of false economy was over. We could afford to spend more in the preservation of our young. The present Government was prepared to make grants in aid of any well-considered scheme submitted by a local authority.

Training of Midwives, Health Visitors, and Nursery School Workers.

Colonel R. J. Blackham described the appalling conditions under which childbirth takes place in India, partly owing to the religious prejudice that the lying-in woman is ceremonially unclean, partly to the belief that fresh air is dangerous to mother and child, and, lastly, owing to the ignorance and superstition of an hereditary caste to whom for centuries custom has consigned the care of all parturient women. Colonel Blackham gave a graphic description of how confinements are usually conducted by these "handy-women" known as *dais*. He went on to show how, at the instance of Queen Victoria, Lady Dufferin, the wife of the then Viceroy, started a fund to provide women doctors in 1885 and how this work has since spread. He described briefly the work which was being done by properly trained midwives in Calcutta, Delhi, Madras, and Bombay, showing that a definite movement is now in progress to combat the social and semi-religious customs which are responsible for the terrible dangers which have hitherto attended childbirth in India.—Dr. A. Souza (India) mentioned that the infant mortality in India was still about 600 per 1000 births.

Dr. Ethel Cassie (chief medical officer for child welfare, Birmingham) followed with a practical paper on the training of midwives and pointed out many of the weak spots and difficulties. The midwife was usually engaged about the seventh month and very little was done in the matter of antenatal inquiries. There were too many vaginal examinations and few midwives practised abdominal palpation. The visits during the puerperium were not sufficiently frequent to prevent delay in summoning a doctor for a rise of temperature. Midwives attended too many cases to do their patients justice. Medical practitioners when called in did not arrange to visit when the midwife was present, and therefore could not instruct her directly. The teaching of infant care to pupil midwives in maternity hospitals lags behind modern standards. The larger training schools have antenatal clinics, but this is not yet general. Independent midwives who are recognised teachers of midwifery cannot give instruction in antenatal work. The pupil midwife must have such instruction from a medical expert. Pupil midwives, during their training, should be enabled to see something of puerperal sepsis and should have practical instruction in the use of silver salts as a prophylactic against ophthalmia neonatorum, and should also be taught how to bathe an inflamed eye. They also needed to learn more with regard to venereal diseases. Above all the training of the pupil midwife failed with regard to the management of the mother's breasts and lactation. The nursery of every training school should be under the direction of a child specialist. All these suggestions implied a longer and more expensive training and if, in addition, the midwife were to take fewer cases her financial position must be by some means improved.

A paper on the training of the health worker by Dr. Janet Lane-Claypon brought up the vexed question as to whether the full training of a hospital nurse was a desirable or necessary preliminary to the career of a health visitor. In the subsequent discussion it appeared that most local authorities expect a health visitor to have the triple qualification of a fully-trained nurse, a certified midwife, and to be the holder of a recognised certificate in child welfare. It was agreed on all hands that whatever the training the personality of the health visitor was of supreme importance.

Miss E. Stevenson (principal of the Rachel Macmillan Nursery School, Deptford) read an interesting paper on these pioneer institutions. These schools need superintendents with a many-sided experience and a considerable power of initiative. The staff comprises, first, the heads of the shelters, whose work is being determined by the experiments now in progress, the Froebel Higher Certificate being one of the qualifications accepted; secondly, the student apprentices who work in the shelters; and thirdly, there is room for a large number of voluntary workers who will profit much by a training of, say, one year in the management of little children.

The afternoon session was devoted to the question of the

Unmarried Mother and Her Child.

Mr. Neville Chamberlain presided at the opening, and was succeeded in the chair by Mrs. H. A. L. Fisher. Mr. Chamberlain pointed out that there were more births in France than in England in 1923, and that there were 73,000 infant deaths in France to 52,000 in England, the infant mortality in France having been 96 while that in England was 69. Infant mortality in England among illegitimate children was, however, more than double that among the legitimate, and the damage-rate was certainly correspondingly excessive.

Dr. Letitia Fairfield, barrister-at-law, in an informative paper, dealt with the legislation of various countries at different times affecting illegitimacy. England was exceptional in the rule of "once illegitimate always illegitimate."

Miss J. E. Higson (Liverpool) spoke on the great need for residential accommodation for the unmarried mother and her child. She expressed her approval of the inspection, at present carried out by the Ministry, of homes for the unmarried mother and her child. One of the great needs was more accommodation in such homes, so that the expectant mother could be admitted during the antenatal period both for physical and psychological reasons. The staff of these homes was often inadequate to meet the strain of the work. Smaller homes, although more costly, were much better. Care should be given to secure that the furnishings were bright and attractive and the dresses worn becoming. The Liverpool guardians were exceptional in having appointed a staff of welfare workers to care for these mothers. Miss Higson pleaded for more sympathetic treatment of the woman who had her second illegitimate baby.

Dr. Julius Levy (U.S.A.), in a paper entitled the Prevention of Foundlings, described the system in vogue in New Jersey. A supervisor of unmarried mother work is appointed, who visits the hospital where the mother is confined, and works out a plan whereby the baby can be kept with, and nursed by, its mother. In about two-thirds of the cases relatives are persuaded to take the mother and her baby. During the last four years 90 per cent. of the babies have remained with their mothers for three months and 76 per cent. for six months. It is claimed that since the scheme was started the infant mortality-rate among the illegitimate babies has been about the same as that prevailing among legitimate.

The keynote of the discussion was that every effort must be made to keep mother and child together. There is, of course, general agreement that this arrangement should hold until the baby is weaned, but the speakers did not throw much light on the problem of how to find a permanent home for the illegitimate child with its own mother.

The discussion on

Child Adoption

on the second day was the complement to the discussion on illegitimacy. Mrs. D. Margesson (London) (hon. secretary of the National Adoption Society), Mr. G. B. Hurst, K.C. (London), and Dr. H. D. Chapin (president of the Children's Welfare Federation, New York), made out an unanswerable case for legalised adoption. England is one of the few civilised countries in which adoption is not yet legalised. If adoption were legalised a large number of homes would be available for the maintenance of derelict children. As Dr Chapin puts it, "Homeless children should be put in the childless homes to the lasting benefit of both." And again, "To be brought up in a precarious manner by the hard uncertain struggles of an unmarried mother without normal home-life and with the stigma of illegitimacy hanging over its head is not a happy outlook" Or to quote Mrs. Margesson: "It is a fact that there is no natural place, economically or socially, for an unmarried mother and her child to live together in a civilised country." There is no need for the National Council for the Unmarried Mother and her Child and the National Adoption Society to remain in opposite camps. There is room for both. There are no doubt a considerable number of cases where the unmarried mother and her illegitimate child can make a good home with relatives. Failing that, surely the legal adoption of the child into a good family is the best solution of the problem.

Lady Nott-Bower mentioned that adopters would not be forthcoming for the child of a mentally defective mother, but surely *no* child should be left to the care of a feeble-minded mother. The remedy for this last problem is obviously the better supervision of mentally defectives.

Another part of the morning session was devoted to discussing the

Overseas Settlement of Children.

Sir Arthur Lawley gave an interesting account of the farm school established in Western Australia by Kingsley Fairbridge, a Rhodes scholar, who took out 25 boys. The scholars now number 200, 100 girls and 100 boys. The school has been wonderfully successful.—Mr. Percy Roberts described the large-scale operations of Dr. Barnardo's homes in sending boys to the colonies and the wonderful success obtained.—Dr. Mildred Thynne (maternity and child welfare medical officer, Bermondsey) described the obsolete Board of Trade regulations with regard to the diet of children on ocean steamers. Fortunately the shipping companies are not content with the Board of Trade's minimum, but Dr. Thynne made out a case for greater attention to this important matter.—Dr. E. W. Morris (the representative of the Australian Commonwealth) described the careful measures which were taken to safeguard the health of children during the voyage to Australia. He further said that among the emigrated children there were no failures. Failures occurred among adult and middle-aged persons owing to faulty selection.

Day Nurseries.

In the afternoon session the Hon. Mrs. Eustace Hills, who presided, dealt with the educational value of day nurseries to the parents who utilised them.—Sir Bruce Bruce-Porter read a paper on the Preventive Side of Day-Nursery Work and Dr. Crichton Miller one on the Psychological Benefit to children of being in a Day Nursery.

The morning session of July 3rd was devoted to the consideration of the

Available Measures for Securing Healthy Pregnancy and Safe Delivery.

The principles on which the new system of preventive midwifery should be founded, as contrasted with the emergency midwifery which has hitherto been the rule, were ably expounded by Lady Barrett. The move which is being made in the same direction in the U.S.A. and the Dominion of Canada was dealt with by Miss C. van Blarcom (New York) and Dr. Helen Macmurchy (Canada).—Dr. E. W. Morris, who presided, uttered a word of caution from the experience of Australia as to the need for safeguarding the proper expenditure of the maternity benefit.—Dr. Amand Routh described the growth of antenatal work in London during the last ten years. Representatives from New Zealand, British Columbia, Singapore, the Leeward Islands, and India described the development of this work in their respective countries.

Among the many important points made by Lady Barrett were the following: We must get rid of the prevalent idea that it is the lot of women to endure. Every lying-in home should be affiliated to a fully-equipped woman's hospital. There should be special sessions at the larger maternity centres for venereal diseases. Gonorrhœa is quite an important cause of puerperal sepsis. Better training of doctors and midwives, especially in the early symptoms which lead to morbidity and mortality, is urgently needed. The causes of abortion have been insufficiently studied, and hospital beds are required for cases of threatened abortion. The education of all sections of the public is necessary in order that the money may be forthcoming for combating the present deplorably high maternal and neonatal mortality.

Propaganda and Visits.

The last session, held under the auspices of the National Baby Week Council, discussed the most effective methods of propagandism on maternity and child welfare. In addition to the ordinary sessions many lectures and visits to institutions engaged in maternity and child welfare work were arranged for the delegates. Special meetings were arranged for Poor-law guardians and by the Eugenics Education Society. The Association of Infant Welfare Centres discussed 'Toddlers' Playgrounds and the reorganisation of health visiting schemes at a special meeting. The annual meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health was held on July 3rd, and all medical representatives attending the Conference were invited to be present. Prof. E. Mellanby opened a discussion on the treatment of babies suffering from malnutrition, and indicated the results obtained by him at the Sheffield Infirmary by the employment of a carefully adjusted vitamin-rich diet.

VIENNA.

(From our own Correspondent.)

Effect of X Rays Upon the Pregnant Myomatous Uterus.

At one of the recent meetings of the Vienna Medical Society Dr. Schilles demonstrated the case of a woman, 43 years of age, who had repeatedly applied for help in order to be relieved from her sterility, which was due to myomatosis. In 1906 and 1912 she had had spontaneous abortion, and in 1918 again severe hæmorrhage had set in. The diagnosis of extensive myomatosis had induced her surgeon to advise excision of the uterus but she refused, and a series of sittings under X rays was instituted in 1920 and 1921, with only partial castration resulting. Patient had hæmorrhages occasionally, and next year she became pregnant. When admitted to the gynæcological clinic in her ninth month, eclamptic attacks supervened and she had to be delivered rapidly, a high forceps extraction being performed. The baby was born in an asphyxiated condition but could be revived. The puerperium was normal for one week, but on the seventh day high fever set in, and a diagnosis of necrosis of myomatous nodules was made. A supravaginal amputation was made and the patient left the hospital later in perfect health. In the specimen a large number of small and large nodules was found. These had no doubt previously hindered impregnation or the development of the fertilised ovum, as has been shown to be the case in similar instances by Olshausen and Lawdan. The application of X rays had, however, produced such a shrinkage of the obstructing myomatous growths that the mucous membrane had regained its capacity to retain the ovum. It is well known that metrorrhagic conditions can be influenced by careful dosage of X rays. The sterility which follows as a rule upon well applied full doses of X rays may be only temporary; one case is known in which after an interval of 14 years, in one of the first cases treated that way, conception took place. Other instances in which women have been rendered capable of bearing a child to full term by means of X rays have already been reported by Steiger, Zangemeister, and Schuhmann.

An Anti-Smoking Campaign.

An appeal to all medical practitioners has just been published, in which their coöperation is demanded in the effort to suppress, or at least cut down, the habit of smoking. In a leaflet, sent to every individual doctor, it is pointed out that over 80 per cent. of all the nicotine contained in the tobacco flakes or leaves goes over into the smoke. According to the pharmacologist Kobert, the poisonous effect of nicotine is equal to that of prussic acid, and affects all the systems of the body—the cardiovascular, alimentary, respiratory, and nervous. In the opinion of Erb (Heidelberg) it is one of the chief ætiologic factors in producing early arterio-sclerosis, and all smokers show earlier or later distinct disturbances of the innervation of the vascular system. Spasmodic conditions, like angina pectoris, dysbasia angiosclerotica (Erb), temporary unconsciousness, neuralgia, vertigo of all types are frequent at the age of 40–50 years in inveterate smokers, also early sudden death due to heart failure. Frankl Hochwart (Vienna) has illustrated the serious dangers to the nervous system in a series of 1500 case-histories obtained from well-to-do private patients, and the pathological changes in sight and hearing, besides the predisposition to cancer of lips and tongue in obstinate smokers, are well known to all doctors. Other students in France, in America, and in Sweden have come to the same conclusion that nicotine is one of the most potent factors in the increasing morbidity of civilised life. The leaflet urges the profession to discourage the custom of smoking in bedrooms and sitting-rooms or in public localities where numerous non-smokers also assemble. Especially where children are concerned, smoking should be strictly prohibited, and adolescents should under no conditions be permitted to indulge in the habit since it tends to promote weakness of the will, apart from harmful effects upon physical development. In subjects prone to catarrhal conditions the inhalation of smoke-laden air is apt to cause further deterioration of the delicate respiratory organs. A characteristic of the modern trend of feminine independence is the unrestrained smoking by girls and women. Their nervous system is easily brought into disorder by an excess of smoking, and there is a group of physicians who attribute female sterility to abuse of tobacco. From an economic point of view, the leaflet says, it is well worth knowing that the daily expense of the Austrian population for tobacco exceeds the annual deficit of all our tuberculosis sanatoriums, some of which had to be closed down for want of funds. The costs of two new tobacco factories erected by the State were not much below that sum. The sums saved yearly by a non-smoking community of 6½ millions would be sufficient to pay the entire Government debts in two and a half years and defray the costs of over 40 per cent. of the annual budget in addition. The appeal to the profession does not intend to inform the doctor of the detrimental effects of smoking, but to induce him to collaborate in the prophylaxis against the evil. Medical men are exhorted to unite in bringing about legislation against juvenile smokers, and to set an example in abstaining from smoking themselves. The leaflet is also intended to be laid out in the waiting-rooms of the doctors, and the signatures of 30 leading professors of medicine appended would seem to indicate that the appeal is not merely faddist propaganda. The ill-effects due to smoking have obviously been magnified, and in some instances ancient surmises, long discredited, have been revived by this circular; but the argument of economy excuses all this.

Public Health Services.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Hull.

Dr. J. W. Fraser reports that the only condition where any deterioration has been found since last year is in the state of the children's teeth. Cleanliness is no worse, nutrition slightly better, there has been no special prevalence of disease, and fewer children have required school meals. 14,169 children were examined in the code groups, 4796 special examinations and 4150 re-examinations being made; 10·3 per cent. of the code group were found to require treatment. A system of payment for treatment at the clinics has been introduced, and the figures available for the first two months of the new system show a marked fall in the number of attendances. Attendances for minor ailments fell from 14,477 in the two months to 12,871, and dental attendances from 1394 to 1296. It remains to be seen whether an apparent fall in the incidence of disease is or is not attributable to the introduction of the payment system. The number of cases of skin disease, which had mounted so high after the war, has now happily dwindled to below pre-war figures. The two school dentists report a continual decline in the state of the children's teeth, a relapse which has steadily been taking place for the last three years. The number of 5-year-old children brought to the dentists' notice during the year suffering from extensive dental caries has been alarmingly large; many of them have exhibited an almost complete absence of enamel formation. It would be interesting to know to what this condition among the 5-year-old group can be definitely attributed, and whether it is a condition noted by school dentists in other parts of the country or is indigenous to Hull alone. The report by Mr. Bates, the organiser of physical training, shows a remarkable extension of out-of-school activities.

School playgrounds can be used between 4 and 6 in the evenings, if necessary. With one exception, every senior department—boys and girls—in Hull sent a class or classes to the baths each week throughout the year. There were 1280 in the learners' swimming classes, and 2218 certificates were issued. Mr. Bates was allowed two months' leave of absence in order to study the work of the Playgrounds Association in Canada and the United States.

Warrington.

In all serious cases of measles in Warrington the parents are offered hospital treatment or the services of a district nurse. Children convalescent from infectious disease are seen by the school medical officer before returning to school, as are contacts with infectious disease suspects and children with sore-throats. The number of deaths among children of school age in the borough was the lowest recorded in the past ten years. The system whereby the nurses deal with cases of minor ailments in the schools has resulted in an extraordinary decrease in the numbers attending the clinic. In 1921 there was a total of 22,203 attendances, against 4150 in 1923. The children are attended to by the nurse twice a week in the schools. Dr. G. W. N. Joseph rightly regards the aim of all modern public health work as educational and designed to strengthen self-reliance. The danger of lessening parental or personal responsibility is borne in mind, and when the cases and the home are suitable they are referred for treatment in their own homes under the supervision of the nurses; 320 cases, most of them pediculosis capitis, were dealt with in this manner.

Margate.

Mr. Rowan McCombe considers that the children of to-day are better fed, better clothed, and cleaner than they were 10 or 14 years ago, although he doubts whether their parents are in any better circumstances. We wish he had been able to include "better housed." In spite of frequent visits to the schools of the school nurse and doctor, uncleanliness has been more prevalent during 1923, and Mr. McCombe deplores the fact that the authorities have no power to cut the hair of children in a verminous condition. The method of excluding unclean children from school and prosecuting the parent for non-attendance he considers clumsy and ineffective, and to use the powers given to the Education Authority under the 1908 Children Act would necessitate the employment of an extra nurse. About 80 per cent. of the parents attend medical inspection; this is encouraging and shows the interest being taken in the school medical officer's work in Margate.

Grimsby.

Here there is no scheme for dental treatment. Twenty-one per cent. of the children examined in the routine group had more than four decayed teeth, but on account of the lack of facilities for treatment only 9·6 per cent., the very worst cases, were referred for treatment. Altogether 4102 children were inspected in the code groups, and 22·08 per cent. required treatment; 12 mentally and physically defective children were reported to the authority during 1923. Apart from six children suffering from non-pulmonary tuberculosis who have been sent to sanatoriums, no provision has been made for cripples. Of nine children "suitable for training in a school or class for the totally blind," three are attending the ordinary elementary schools, and four coming under the same category are apparently receiving no instruction at all; two are in attendance at certified schools or classes for the blind. Special provision for defective children is urgently required here. Dr. B. C. Stevens reports more cases of malnutrition, but bad cases are the exception.

Cambridge.

Dr. A. J. Laird reports that the most notable features of the work for 1923 have been: (1) the steadily increasing use made of the clinics; (2) the greater readiness of parents to obtain treatment; (3) the elimination of ringworm as a serious cause of loss of attendance; (4) the maintenance of a high standard of cleanliness. The attendance at his clinic showed an increase of 611 children, 2523 children having been treated there. Dr. Mabel Gurney, the assistant medical officer, expresses the opinion that the slight reductions in the heights and weights indicate a falling off in the general physique of the children since the war, and attributes this to unemployment. According to the figures given, while there are fewer above the average, 8·7 per cent. against 15 per cent. in 1914, there are also fewer below, 4·3, as against 17 per cent. in 1914. Dr. Gurney comments on the insufficient amount of sleep some children get. Parents do not always realise the need to overcome the opposition every child makes to being sent to bed early. Among the older girls many demands are made upon their spare time by music lessons, Girl Guide and other meetings. Dr. Gurney has here laid her finger on an important point. It seems unfair that these activities, which are generally part and parcel of the school life at secondary or private schools, should only be available in the evenings for the elementary school child, who is often overburdened with home duties as well. It is impossible for elementary school-children to get to bed in time if they are intelligent enough to take an interest in activities outside school; such activities should be incorporated in ordinary school life. The number of children examined at dental inspections during the year was 4923. It was found that the percentage of children with four or more teeth decayed was 8 per cent. less than in 1922. Dr. Laird has gone very fully into the question of the prevention of dental decay. He has come to the conclusion that tooth-brush drill is impossible in schools owing to: (1) expense of outfit; (2) lack of suitable accommodation; (3) inutility, except from an educational point of view, and he suggests that instead tooth-brushes should be supplied to children at cost price. It is possible, however, that the educational value of tooth-brush drill alone is worth the time and money spent on it.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 28TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 65; scarlet fever, 1356; diphtheria, 692 (as against 651 of the previous week); enteric fever, 181 (as against 133 of the previous week); pneumonia, 677; puerperal fever, 46; cerebro-spinal fever, 11; acute poliomyelitis, 10; acute polio-encephalitis, 2; encephalitis lethargica, 132 (as against 161 of the previous week); ophthalmia neonatorum, 116. There were no cases of cholera, plague, or typhoid fever notified during the week. Of the 65 cases of small-pox, 24 were notified from the county of Derby (Derby 9, Chesterfield 12, Chesterfield R.D. 2); 2 from the county of Durham (Stockton-on-Tees); 9 from Middlesex (Willesden); 11 from Northumberland (Ashington); 2 from Nottingham (Hucknall); 13 from Yorks, North Riding (Middlesbrough 11, Eston 2). Of the cases of encephalitis lethargica, 26 were notified from the County of London (Camberwell 1, Finsbury 1, Fulham 2, Greenwich 1, Hackney 2, Hammersmith 1, Holborn 1, Islington 3, Lewisham 1, Paddington 1, St. Marylebone 3, St. Pancras 2, Shoreditch 2, Southwark 1, Stepney 3, and Woolwich 1); 6 from the county of Durham (Gateshead 3); 4 from Essex (Walthamstow 2); 5 from Bristol; 18 from Lancaster (Liverpool 7, Manchester 1); 8 from Middlesex (Tottenham 4); 2 from Norfolk (Norwich); 2 from Newcastle-on-Tyne; 13 from the county of Warwick (Birmingham 11); 12 from Yorks, West Riding (Leeds 3, Sheffield 3); and 2 from the city of York.

Deaths.—In the aggregate of great towns, the deaths from influenza numbered 30, while the deaths from diphtheria fell from 29 to 20.

THE Chelsea Hospital for Women has received from the Court of Common Council of the City of London £105 towards the fund (£20,000) being raised by the Lord Mayor for the completion of the Nurses' Home and opening of additional wards; £8300 are now required.

Correspondence.

"Audi alteram partem."

DISINFECTION IN SCARLET FEVER AND DIPHTHERIA.

To the Editor of The Lancet.

Sir,—Dr. Duncan Forbes's paper in your last issue opens up again a field of discussion which is much wider than the transference of responsibility for disinfection from the local authority to the mother of the infected child, and for this reason, although with some hesitation, I submit the following observations.

Dr. Forbes does not suggest that the infectivity of scarlet fever or diphtheria is negligible. On the contrary, his pamphlet of 1909 gives very specific instructions to the housewife how to deal with infected articles. She, however, has her limitations; "books are difficult to disinfect" and they should be collected by "the Public Health Department." But just as some housewives would find it difficult to disinfect books, so many more (in some districts at least) would find it difficult to carry out the surgical spring-cleaning recommended, and in individual cases the decision would resolve itself into a question of expediency to be determined by the domestic facilities for carrying out the requirements.

In the argument, however, considerable importance is attached to the healthy carrier and the missed case in the spread of disease, and it is just precisely how far either is to be accepted as valid for all infections not otherwise explained that their use as a plea for reduced stringency in disinfecting measures becomes important. No one, indeed, questions the importance of either as a factor in spread, but will both together explain the recurring extensive waves of scarlet fever through several decades, or the rise in diphtheria, in Scotland at least, since the early years of the century?

Moreover, is a healthy carrier, even with his wider range of action, likely to be more effectual in transmitting disease than the clinically diseased person at close range? The argument would be valid had we evidence that these diseases spread by contact only. But contact alone will not explain even the autumnal rise in scarlet fever, still less its recurring extensive prevalence at intervals of years. And the increase in prevalence of diphtheria in Scotland took place after the healthy carrier had already established for himself a place in such inquiries. Both diseases illustrate, indeed, how very elementary is our knowledge of the life-history of the infecting organisms.

As a further illustration, in which the theory of the healthy carrier has also been advanced as an explanation of spread, take the present distribution of encephalitis lethargica in this country. What is the picture presented? A few cases are recognised widely separated from each other and with no discoverable association between them. Subsequently, in the neighbourhood of some, but not all of them, other cases occur, equally detached. It is rare that two cases occur in one family, but aggregations of cases within comparatively limited fields are not uncommon. Are we to ascribe this massing to healthy carriers in the district, when the clinically infected person almost uniformly fails to infect his own family? A spot map of such illustrations of endemic plague as we have experienced in this country would present just such features as I have tried to suggest of the distribution of encephalitis lethargica. Did we not know of the part played by the rat and its parasite, sporadic cases of plague would excellently illustrate the theory of the healthy carrier.

Our knowledge of some of the channels through which infection spreads is pitifully inadequate to explain the fluctuations in disease prevalences which occur, and it seems to me that until we have a wider knowledge of the life-history of infecting organisms, every step which would tend to suggest that infectivity was a comparatively trivial matter is to be taken in view of the whole problem and not of any particular aspect of it.

We dismiss the desquamating child from hospital because there would appear to be some evidence that certain stages of desquamation are not associated with infectivity. We find cases of scarlet fever grouping themselves round a particular class or department of a school and proceed to search for the desquamating child, often finding him without suggestive throat condition, and stop the occurrence of further cases by removing him. As facts of observation, these two illustrations appear to be contradictory, but they would undoubtedly find a common explanation did we know the life-history of the infecting organism. This has, I fear, travelled far beyond Dr. Forbes's suggestion of a comparative trial of domestic *v.* municipal disinfection, although it represents to me, at least, the mental attitude in which I think the question should be approached.

Finally, is it not worth asking what would be the effect on the mind of the housewife of proclaiming an infectivity which was to be combated by a restricted spring-cleaning?

I am, Sir, yours faithfully,
A. K. Chalmers,
July 5th, 1924. Medical Officer of Health, Glasgow.

To the Editor of The Lancet.

Sir,—Few readers will be inclined to disagree with the conclusions and practice explained by Dr. Duncan Forbes in his communication on the subject of disinfection, and one might almost feel confident in expressing the view that the practice which he indicates is that which is followed in a very large number of instances. The interesting volume published by Dr. C. V. Chapin, of Providence, U.S.A., in 1910, on the *Sources and Methods of Infection* is well worth perusal in connexion with Dr. Forbes's subject.

It will not be lost sight of, however, that in certain localities, for example, amongst the dockside labouring population of a large seaport which, in its habits and customs, differs widely from those of a fashionable health resort, the practice of disinfection goes far to encourage domestic cleanliness, and the processes which destroy vermin of various kinds are far from being without useful effect.

I am, Sir, yours faithfully,
E. W. Hope,
July 7th, 1924. Medical Officer of Health, Liverpool.

"INDUCTION" OR "CAUSE" OF CANCER.

To the Editor of The Lancet.

Sir,—Dr. A. Leitch (June 28th) is pleased to have his little jest about my lamb, but it is only kind to inform him that this is fast growing into a sturdy sheep, and will soon be strong enough to butt anyone who treats it disparagingly! This is not merely fond parental opinion; it is also the view of several biologists and pathologists fully competent to judge. The story of the photographic expert is highly amusing, but, unfortunately, it appears to me to be distinctly unapt, if meant to apply to my case. Had I ever ventured to discuss the clinical and macroscopic aspects of malignancy, the matter would be different. But observation of cases of cancer is not an indispensable requisite for the study of the behaviour of the cancer cells themselves. Dr. Leitch, as an eminent pathologist and bacteriologist, will know in how very many instances the actual cause of a disease can be determined in the laboratory without any visit to the bed-side being necessary.

As a matter of fact, my paper on malignancy (*Jour. R.A.M.C.*, vol. xli., October, 1923) was based in part on valuable sections most kindly lent me by Dr. Leitch himself; and what I have seen is there to be seen by others. It is all a question of being able *rightly to interpret what is happening!* I know quite well, of course, that microscopical study can only furnish indications, not proof. But may I just add, in view of the trend of Dr. Leitch's remarks, that, while I would not in the slightest degree minimise the importance of the macroscopic study of malignant growths, I think the method of pondering the appearances shown by the cancerous cells, under a high power of the microscope—a study which seems to have almost gone out of vogue in these days—is one which can still give most helpful results. Particularly would this seem to me to be the case, if we remember that the malignant *condition* is the expression of some unusual manifestation of cell life—to which view, I take it, Dr. Leitch would subscribe. Has any other method of attacking the problem brought us anywhere near knowledge of the actual cause? Ought one, therefore, to neglect any line which may bring us nearer to the truth?

I am, Sir, yours faithfully,

London, June 30th, 1924. H. M. WOODCOCK.

SIMMINS APPEAL FUND.

To the Editor of THE LANCET.

SIR,—Under the above heading a remark occurs which might imply that the benefits derived from the Royal Medical Benevolent Fund are enjoyed by subscribers only, and that in this sense the fund is a provident institution. On the contrary, the annual report sets out the operation of the Fund in the following words: "The Fund is a general charity, the benefits of which are *open to all* deserving cases without restriction. Other medical charities are for the most part local, and of the nature of provident clubs, the benefits of which are restricted to subscribing members."—I am, Sir, yours faithfully,

CHARTERS J. SYMONDS,
Hon. Treasurer, R.M.B.F.

11, Chandos-street, Cavendish-square, W.,
June 30th, 1924.

SOME FUNDAMENTAL FACTORS IN THE SPREAD OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—May I answer Dr. E. W. Goodall's kindly criticisms in THE LANCET of June 28th of my paper on the above subject. He quotes a paragraph which, he says, implies that "several infectious diseases, no matter what nature, could be nursed safely in the same ward." There was no intention of meaning this, and it was considered that the addition—"provided the beds *are far* enough apart"—enabled the statement to be generalised. Under the ordinary conditions of bed isolation treatment I accept unreservedly Dr. Goodall's amendment of the sentence—namely, "that it is possible so to nurse several different diseases." Bed isolation was introduced to illustrate a principle; I had no intention of discussing its practical limitations. I had read the discussions on bed isolation, which Dr. Goodall referred to, and found much in them to support the theories brought forward in my paper. I realise that in beds 9 *or* 12 feet apart certain cases, such as those suffering from chicken-pox, cannot safely be nursed in company with other patients. Dr. Goodall further thinks that I imply that "infection is to all intents and purposes always conveyed by heavy droplets at short range." The actual words used in the paper were: "The short-range jet of heavy droplets is the *usual* means by which so-called contact infection is acquired." Perhaps I should have added, "in many of those conditions in which the dependent organism is disseminated in buccal and respiratory discharges of the host." But I hoped the whole context suggested this limitation. The above proposition is not proved, but one of the objects of the paper was to indicate evidence in favour of it.

Dr. Goodall thinks that a term allowing for microbic multiplication should be introduced into the formula for velocity of infection. When either the resistance of the host or the infective intensity of the parasite increases or diminishes, a negative or positive acceleration of the velocity of infection will result, but the formula as it stands fulfils its purpose, which is to show as simply as possible how time can be a factor in acquiring parasitic infections. The use of round numbers was a clear method of explaining the principle of velocity of infection. It is unthinkable that anything so simple should actually happen, as that, of 100 microbes received, 50 are completely destroyed and 50 retain their infective intensity unchanged and that no multiplication occurs throughout the chosen unit of time. The original number of microbes may even increase; at the same time, their infective intensity may actually diminish under the action of the environmental conditions found in the host. This, however, is only guessing because what really happens is unknown.

I think Dr. Goodall overlooked my attempt to define virulence, which was as follows: "For the present purpose virulence may be defined as the extent to which a parasite can injure the host"—a purposely elastic definition which would have been improved by inserting "average susceptible" before host.

Perhaps an apology is due to Dr. Goodall and your readers for attempting to deal with so large a subject in so short a space. In the opening paragraphs of the paper I confessed I would have to be brief and dogmatic. The object of the paper was to indicate certain principles; there was no time to discuss their limitations in practice, or the application of them to special cases. I would like to add that most of the theories brought forward were, in the main, deduced from the experience gained during the 1918 influenza epidemic. In the case of diphtheria the Schick test enabled much more definite evidence to be collected in favour of the conclusions I arrived at from the study of other diseases.

I am, Sir, yours faithfully,

S. F. DUDLEY.

Royal Naval College, Greenwich, July 3rd, 1924.

THE FUTURE OF THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I should be obliged by your permitting me to add a few remarks to the editorial note on the above-mentioned subject which appeared in THE LANCET of May 31st, 1924.

Some influential daily papers have been clamouring for an expeditious ratification of the recommendations contained in the Lee Commission's Report. The Commissioners themselves, probably prompted by the strained conditions they found during their comprehensive and invaluable investigation, also urged an early decision regarding their proposals. All who are familiar with the present position of affairs must be in full sympathy with a desire to arrive at a settlement of the many questions dealt with as soon as possible. Nevertheless, many will consider that this is a case in which wisdom lies in making haste slowly.

The report proposes the introduction of changes of grave importance in the All-India Services on the civil side, and particularly in the Superior Services of Provincial Governments. We are specially concerned with the proposed abrogation of the Indian Medical Service and the assistant surgeon branch of the Indian Medical Department, a change which common sense alone indicates should not be made without complete deliberation as to its immediate and ultimate effect on medical work in India.

I will not burden your readers with any opinion on the proposals contained in the Lee Commission's Report regarding the Medical Services, beyond stating that they provide for what should prove to be a perfectly organised and efficient military medical service in India if it includes the assistant surgeon branch of the Indian Medical Department (no adequate reason appears to be given for not including it), but the changes proposed for the Civil Medical Service are such as many experienced officers of the Civil

Services may consider will lead to stagnation, and possibly to rapid retrogression of Western medicine in India. The medical administration of the military side deals with approximately 300,000 men; the civil medical administration deals with a few hundred millions of people. Whilst undue haste is to be deprecated in dealing with the Lee Commission's Report, it is earnestly hoped that it will not share the fate of some of its predecessors, which became obsolete before any action was taken on them. Political opinion in India is shifting rapidly. Many serious questions hang on the decisions to be arrived at—recruitment, financial relief, leave, &c.—of the European services; the settlement of these should meet with no unnecessary delay.

The Lee Commission's Report will not be discussed in the Central Legislative Assembly in India until next September, and I understand that neither the Secretary of State for India nor the Government of India will take any action on the proposals until this discussion is over. It is highly probable that certain Indian politicians will attempt to withhold the grant of concessions to the European Civil Services until their demand of February last for further constitutional advance has been conceded.

I am, Sir, yours faithfully,
P. HEHIR,
Major-General, I.M.S. (ret.)
Westward Ho! July 5th, 1924.

SPINAL ANALGESIA.

To the Editor of THE LANCET.

SIR,—I was extremely interested in the article by Mr. B. H. Slater on spinal analgesia in THE LANCET of June 21st and your comments thereon. I think, however, that the views put forward are unduly optimistic. For instance, the general statement is made that "it is safer than general." While admitting that reliable statistics are extremely difficult to obtain, I doubt whether the most enthusiastic "spinal" advocate would claim a lower total mortality due to the method than 1 in 500. As a matter of fact, I know of several series of cases showing a considerable higher mortality. Turning now to general anæsthesia, the average immediate and remote mortality due to the anæsthesia (partly or entirely) ranges from 1 in 1500 to about 1 in 4000 in most London hospitals. Again, the statement is made that "there are no chest complications." I have myself seen four cases of serious chest complications following spinal analgesia, one of which was fatal. It is true that pulmonary complications are, on the average, less with spinal than with general anæsthesia, but is this not due to the fact that the former method is seldom used in operations involving much interference with the diaphragm and adjoining peritoneum—e.g., gastrectomy, cholecystectomy, splenectomy, &c.?

Mr. Slater also says that "there are practically no anæsthetic anxieties." I think that most anæsthetists will agree that spinal cases involve more worry than do "general" ones. Few situations are so unpleasant as to have a spinal patient with a progressively falling blood pressure in spite of an exaggerated "Trendelenburg" position. Complete muscular relaxation is also claimed as an advantage of spinal analgesia, but is by no means confined to this method. Endotracheal gas-oxygen with a surprisingly small amount of added ether provides the most complete relaxation that can be demanded, and does so with absolute certainty, owing to the perfectly clear airway which is at all times assured.

Finally, it is suggested that if the technique be correct, there are no disadvantages to spinal analgesia except some extra work. The following complications have all occurred, some of them fairly commonly: (1) Pulmonary troubles, including bronchitis, pneumonia, embolism, and acute pulmonary œdema. (2) Sudden cardiac failure during operation. Practically all cases show marked fall of blood pressure soon after the injection of the drug. (3) Alimentary complications. Vomiting is not uncommon during the operation and may prove embarrassing. Post-operative paresis of the gut and incontinence of fæces are rarer but more dangerous events. (4) Urinary complications. Loss of bladder control has occasionally led to ascending infection. (5) Various ocular paralyses leading to persistent strabismus, diplopia, and ptosis. (6) Persistent headache. One other indirect complication is reactionary hæmorrhage. Where the fall of blood pressure is marked, vessels may not bleed at the time of operation, but begin to leak when the patient is back in bed. Such a case proved nearly fatal quite recently.

It may be contended that these unfortunate events only occur when the technique is faulty. This, however, is not so, as the mortality has not been appreciably lowered by using "heavy" solutions or by employing the various substitutes for stovaine which are now on the market. I think that enough has been said to indicate that while spinal analgesia may be an admirable procedure for selected cases in skilled hands, yet it is by no means devoid of risk.

I am, Sir, yours faithfully,
C. LANGTON HEWER.
York-terrace, Regent's Park, July 4th, 1924.

THE WORK OF WELFARE CENTRES.

To the Editor of THE LANCET.

SIR,—Welfare centres have undoubtedly been of enormous value in reducing infant mortality, and of still greater value in raising the physical standard of the children, but I venture to suggest that more could be done if it were possible to standardise the advice given by doctors, midwives, and health visitors. All these are advising to the best of their ability, and the advice they give necessarily varies with their experience. Most of the work at an infant welfare is concerned with healthy infants, those that are really sick being taken usually to hospitals for treatment. The mothers of the healthy infants desire to know if what they are doing is the best for their babes. It is reasonable to suppose that the average infant of healthy parents is born healthy, and that subsequent minor ailments are due to lack of knowledge of the best way to feed, clothe, and house the infant on the part of the mother. Infants are like any other healthy young animals, and at any rate up to nine months could all be reared exactly alike without any distinction being made between them as regards diet and clothing.

As examples of the type of question asked by mothers, I select the following as illustrating the need of a standard.

1. What is the best time-table of infant feeding at birth? The answers vary from two-hourly during the day and twice at night, to five feeds a day at four-hourly intervals and none at night. On the latter time-table the infants thrive well and there is no question which is the more restful to the mother.

2. At what age should a healthy baby be weaned, and when should it be given such articles of diet as meat, potatoes, bread, and so on?

Here the variation in the advice given by individuals must be very great, so great, in fact, that the opinions of two doctors each running a welfare centre in the same town can be, and often are, diametrically opposed to each other, while midwives in the same centre each have their own opinions. These opinions are not concerned with the treatment of sickness about which there must be very often wide differences, but with the diet of a healthy child. I expect to be considered wrong in so advising, but I find that meat, chopped fine, is digested and well liked by many infants from nine months upwards.

There is, too, a great sum of money wasted annually in almost every household upon various medicines, particularly aperients. These latter are given for no reason whatever, more often than not with the mistaken idea of keeping a baby fit. If there should be a reason, what is required is some alteration in the diet rather than an aperient. They certainly do far more harm than good, when given indiscriminately, and can quite reasonably be supposed to lower the physique, and make the infant more liable to piles later on in life. The ideal should be a normal action of the bowels without any medicine whatever, when if an aperient should be necessary for illness at any time its efficiency is so much greater. As an extreme instance, a mother informed me last winter that she was unable to afford any woollen garments for her children, but stated, with evident pride, that she was able to afford a 3*s*. 6*d*. bottle a week of some lung tonic to prevent them catching colds.

It is suggested that some competent body should issue a small cheap book stating exactly what is the ideal life time-table of a *healthy* infant, breast-fed and bottle-fed, with practical and economical advice *re* clothing, &c., from birth up to 2 years. I believe this would fill a much desired want on the part of mothers and welfare staffs and might obviate some of the defects of infant life which still permit a mortality of 69 per 1000 births.—I am, Sir, yours faithfully,

Southampton, July 6th, 1924. A. G. G. THOMPSON.

THE PROBABLE DUAL CONSTITUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—It has been assumed that since insulin administered by the mouth does not induce a fall in the sugar-content of the blood similar to that which results when it is given intravenously or hypodermically, it has no influence upon metabolism, and is either not absorbed by the mucous membrane of the alimentary tract or is destroyed by the digestive secretions. The metabolic experiments on animals upon which I have been engaged for some time in association with Mr. H. A. H. Howard, B.Sc., suggest that this conclusion is not entirely correct, for from observations on the respiratory quotient in a series of guinea-pigs and rats to which insulin had been given by the mouth it was found that, although there was no diminution in the blood-sugar, the effects of a subsequent injection of adrenalin were counteracted in much the same way as in animals to which insulin had been administered hypodermically. It would therefore seem that insulin may be absorbed through the walls of the alimentary tract, but that its properties are modified in the process, or, what is more probable, a fraction which promotes the utilisation of sugar by the tissues is destroyed, while another fraction which is able to neutralise the glycogenolytic effect of adrenalin passes into the circulation unchanged.

Six guinea-pigs, with an average fasting respiratory quotient of 0·73, gave an average respiratory quotient of 0·81, with the usual drop in the blood-sugar, after two units of insulin had been injected subcutaneously, and 0·81, with increases in the blood-sugar ranging between 0·14 and 0·18 per cent., after a hypodermic injection of 0·25 c.cm. of adrenalin. When insulin and adrenalin were injected in succession there was little or no change in the sugar-content of the blood or in the respiratory quotient if the doses were correctly adjusted, showing that the hypoglycæmic effect of the adrenalin had been neutralised by the insulin and that less carbohydrate was being utilised than when either was given separately. In the same series of animals the administration of two units of insulin by the mouth at hourly intervals for three hours was found to have no influence upon the sugar-content of the blood or upon the respiratory quotient, but when a hypodermic injection of 0·25 c.cm. of adrenalin was given 15 minutes subsequently the increase in the respiratory quotient, which should have developed if the adrenalin were acting unchecked, failed to appear, the average for the six animals working out at 0·735, or practically the normal fasting value. It was therefore evident that, although insulin given by the mouth had no effect upon the sugar-content of the blood, it was capable of preventing the glycogenolysis consequent upon the introduction of a potent dose of adrenalin into the circulation.

Similar results were obtained with white rats. The average respiratory quotient of three of these animals worked out at 0·77 in the fasting state. A hypodermic injection of two units of insulin produced a characteristic fall in the blood-sugar and a rise in the respiratory quotient to 0·82, while a hypodermic injection of 0·25 c.cm. of adrenalin was followed by an increase in the sugar-content of the blood and an average respiratory quotient of 0·82. Two units of insulin given by the mouth for three hours produced no alteration in either the percentage of sugar in the blood or in the respiratory quotient, and when 0·25 c.cm. of adrenalin was injected a quarter of an hour later there was still no change, an average respiratory quotient of 0·77 being obtained, demonstrating that in these animals, as in guinea-pigs, insulin administered by the mouth was capable of influencing carbohydrate metabolism, although only so far as its anti-glycogenolytic properties were concerned.

If, as these experiments indicate, the anti-glycogenolytic fraction of insulin taken by the mouth enters the circulation, while the sugar-utilising fraction is destroyed, or at any rate is not absorbed, it is possible to account for the beneficial effects claimed to have resulted in some cases of diabetes from the oral use of crude extracts of insulin, such as that of Mackenzie Wallis, and from the administration of raw pancreas, or preparations of the gland, by the mouth, for the anti-glycogenolytic portion being effective such treatment would be likely to be helpful where the hyperglycæmia was dependent upon defective storage of glycogen and there was no interference with sugar utilisation. It would, however, be of little or no value in cases in which there was defective utilisation as well as over-production of sugar, thus explaining the failure of oral treatment with pancreatic preparations where actual disease of the pancreas existed.

I am, Sir, yours faithfully,

July 4th, 1924. P. J. CAMMIDGE.

DEAFNESS IN SCHOOL-CHILDREN.

To the Editor of THE LANCET.

SIR,—May I, as one who has had some experience of the needs of the deaf child in elementary schools, be permitted to comment upon the report of Miss E. Lowry's paper in THE LANCET of July 5th (p. 20)? What I have to say may be best summed up under five heads.

1. There should be more adequate provision for removal of tonsils and adenoids, both at hospitals and in school treatment centres throughout the country, and the cases operated upon should be followed up.

2. These operations should be done by experts. In my experience many such operations are inadequately performed, and it is quite common for mothers to state that their children's deafness was "made worse" by the treatment. Moreover, it is by no means uncommon to find children who have been operated upon not twice, but three times. In many cases, also, the operation appears to have been the be-all and end-all, the deafness being left to get well by itself.

3. In school treatment centres, ear conditions should be treated by *specialists*. Harm has been done by classing ear troubles as "minor ailments," which they most distinctly are not. There is no dearth of competent young specialists to take charge of these centres.

4. Efforts should be made to deal with the child of pre-school age, with the definite view to preventing the conditions which lead to deafness.

5. More effort should be made to discover cases of early deafness in the schools. This, as I have pointed out repeatedly, could be done by introducing a whisper test during the vision-card test; or, as in France and Chicago, by means of games. I pointed this out in my "Plea for the Deaf Child" two and a half years ago (THE LANCET, 1922, i., 1027). These

tests are best done by the teacher, whom the children know and trust, rather than by the doctor, with whom they are apt to be shy. Children found wanting can be handed to the medical authority for more detailed examination. Deaf children could thus be discovered when treatment is of use and a large number of cases of deafness could thus be prevented. At present, these children go unrecognised, often until too late.

I may add that it is a matter of great gratification to me to find that the attention of otologists is becoming aroused to the necessity of prevention. I have been preaching it for the past 15 years, as has my friend Dr. Kerr Love in Scotland.

I am, Sir, yours faithfully,
MACLEOD YEARSLEY, F.R.C.S.
Wimpole-street, W., July 7th, 1924.

RESEARCHES ON LEPROSY AND THEIR BEARING ON THE TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—May I draw attention to a statement in Sir Leonard Rogers's lectures (THE LANCET, June 28th, p. 1297) in which he credits me with the statement that "the addition of 3 per cent. solutions of sodium gynocardate, morrhuate, or oleate to a pancreatic extract doubled the fat-splitting effect of the pancreatic lipase on an emulsion of olive oil." The accelerating action of sodium oleate on lipase varies considerably according to the percentage strength of the solutions used, and so far from using 3 per cent. strength solutions, 0·9 per cent. strength solutions were used in my experiments. My statement in the paper[1] referred to by Sir Leonard Rogers is "Systematic investigation of sodium oleate had previously shown that the accelerating action on extract of pancreas varies considerably according to the percentage strength of the solutions used; graduated amounts added to the extract show also a gradual rise in values up to a maximum, falling ultimately to nothing. I chose, therefore, a 0·9 per cent. solution of sodium oleate which had given good results formerly, and the same percentage solutions of sodium morrhuate and sodium gynocardate, using 1 and 2 c.cm. amounts of these solutions." Obviously the matter is of importance also in therapeutic dosage. He says further that these experiments in vitro led me to suggest a stimulating action of tissue lipolysis in part explanation of the therapeutic effect of sodium morrhuate and sodium gynocardate on acid-fast bacilli, and led him to investigate the possibility of these substances also stimulating the production of fat-splitting lipase in the blood of leprosy and tubercle cases, whereas, as a matter of fact, in my paper, after giving the actual results in my experiments in vitro, I went on to say that in view of the ascertained action of sodium oleate in vivo,[2] "it would seem reasonable to infer a direct stimulating action of tissue lipolysis in, at any rate, partial explanation of the therapeutic effect of sodium morrhuate and of sodium gynocardate, in addition to a direct destructive action claimed for both (Rogers) or for the chaulmoogrates alone (Walker and Sweeney) on acid-fast bacilli."

I am glad to see the confirmation of the lipase theory by Sir Leonard Rogers in the particular case of leprosy, which I have so long pointed out and maintained in cancer, tuberculosis, and other infectious diseases. I may, perhaps, be permitted to add that in 1912 I showed that in recovered tuberculosis the lipolytic activity of the serum is increased. Somewhat later it was found to be decreased in the acute stages, as well as (1914) in T.B. infected guinea-pigs and rabbits examined in the bacteriological laboratory, King's College. In my culture experiments also lipase killed tubercle bacilli.

I am, Sir, yours faithfully,
J. A. SHAW-MACKENZIE, M.D. Lond.
London, July 4th, 1924.

Obituary.

CHARLES HUNTER STEWART, D.Sc., M.B., C.M. EDIN.

BY the death of Dr. Charles Hunter Stewart, professor of public health and sanitary science and director of the John Usher Institute of Public Health, the University of Edinburgh has suffered another loss. Although he had been in poor health for some time, his death on June 30th at his residence in Melville-street, Edinburgh, came quite unexpectedly.

Prof. Stewart was born in Edinburgh in 1854, and educated at the University of his native city, while later he studied extensively on the continent. He first underwent training as a pharmaceutist, but, forsaking materia medica and chemical pharmacy, he applied himself with marked success to the study of experimental science and medicine, graduating Bachelor of Science in 1882, Bachelor of Medicine in 1884, and Doctor of Science in 1894. In 1880 he won the Hope Prize Scholarship in organic chemistry, and four years later the Mackay-Smith scholarship in chemistry. His early scientific training made him a keen observer and a most painstaking investigator. When in 1894 the University of Edinburgh decided to institute a public health laboratory in connexion with the chair of forensic medicine he was chosen by Sir Douglas Maclagan, then professor of medical jurisprudence, to organise and conduct the instruction in it. In 1898 he was appointed to the newly founded Bruce and John Usher Chair of Public Health, and he occupied that chair till his death. In 1902 he became also director of the Usher Institute of Public Health, to the planning and arranging of which he devoted a large amount of time and thought, the result being the provision of laboratories, which at that time were regarded as perhaps the finest in the country.

His colleague, Dr. J. Buchanan Young, writes: "In experiment Prof. Stewart was resourceful, and above all accurate, and he demanded the same accuracy in working from those whom he trained. As a young man he had worked hard, and he never failed to impress on his students the necessity for hard work if success was to be attained, and he took a keen interest in following the careers of those whom he had taught. His prolonged study in continental laboratories and his vast experience in laboratory work made him quick to appreciate improvements in processes and methods, but before any new methods were introduced into his courses of instruction they had to be thoroughly tested by himself as to accuracy of the results given. For many years he was well known and much sought after as an expert witness before the Scottish courts in river pollution cases, and in reference cases involving special knowledge of water-supply, &c. To the investigations connected with these he devoted a large amount of time and energy. The number of experiments he conducted, and the amount of labour and time he expended in satisfying himself as to the soundness of the views he expressed in evidence, were only known of by those who were associated with him in such work. His favourite reply when asked if it was absolutely necessary to make a certain experiment, which to the inquirer seemed somewhat troublesome, was 'Prove all things'! In later years he devoted himself largely to the epidemiological and statistical departments of public health. His grasp of figures was marvellous, and his memory for figures rather 'uncanny.' As a lecturer he was emphatic in style, interesting, and insistent on salient points. He had a quiet, somewhat 'pawky' humour, and those who met him in private life found in him a most interesting conversationalist, willing to discuss practically any subject. During 40 years as a teacher in the University (26 of these as professor of public health) he had seen many changes in the Edinburgh Medical School, and had taught a very large number of students. We who remain are all the poorer by his passing."

In 1888 Prof. Stewart married the eldest daughter of the late Mr. G. Gorden Gibson, an Edinburgh civil engineer. Mrs. Stewart died in 1905, and seven years later Prof. Stewart married a daughter of the late Mr. Robert Somers, of Thrushville, Stirling, who survives him, and to whom we offer our sincere sympathy.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs. H. J. Chater and R. W. G. Stewart to be Surg. Capts.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Comdr. W. E. Harker to be Surg. Capt.

Surg. Lt. Comdrs. J. B. Ronaldson and T. Turner to be Surg. Comdrs.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majs. and Bt. Lt.-Cols. to be Lt.-Cols.: D. S. Skelton, vice Lt.-Col. A. D. Jameson, to ret. pay; P. G. Easton, vice Lt.-Col. A. R. Greenwood, to ret. pay; and P. Davidson, vice Lt.-Col. and Bt. Col. F. McLennan, to ret. pay.

Maj. B. H. H. Spence is restd. to the estabt.

ARMY RESERVE OF OFFICERS.

2nd Lt. R. K. Wilson, late R.F.A., to be Lt.

MILITIA.

Capt. G. F. V. Leary to be Maj.

TERRITORIAL ARMY.

Capts. G. L. Malcolm-Smith (late R.A.M.C., S.R.), and D. S. Jones (late R.A.M.C.) to be Capts.; D. P. Levack and C. E. W. Bower to be Lts.

ROYAL AIR FORCE.

Squadron Leaders W. W. Shorten and F. N. B. Smartt to be Wing Comdrs.

Flight Lts. T. Montgomery and H. L. Burton to be Squadron Leaders.

Flight Lts. J. Craig and H. C. Perkins to be hon. Squadron Leaders.

Medical News.

UNIVERSITY OF OXFORD: *Radcliffe Scholarship in Pharmacology.*—The Master and Fellows of University College have awarded the Radcliffe Scholarship in Pharmacology in equal shares to Thomas C. Hunt, Magdalen College, and Alice D. K. Peters, St. Hugh's College, whose work was reported by the Professor of Pharmacology to be of equal merit.

Welsh Memorial Prize.—Dr. Lee's Professor of Anatomy has reported to the Vice-Chancellor that he has awarded the Welsh Memorial Prize for the best set of anatomical drawings in relation to human anatomy to Perer M. F. Bishop, Trinity College.

In the recent Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery, the following candidates passed the undermentioned subjects of the Final Examination :—

Materia Medica and Pharmacology.—J. W. Alden, B. H. B. Bettington, M. D. Bower, G. Campbell, N. Chilton, J. H. Chitty, R. T. V. Clarke, P. F. Cluver, G. H. Crisp, D. M. Dunlop, J. A. Eyres, A. C. Gairdner, P. S. Hamilton, H. E. Harding, R. Illingworth, J. H. Kennedy, G. L. M. MacElligott, C. W. MacKenzie, R. G. Mathews, J. C. Neely, B. V. O'Connor, F. G. Parker, R. C. Probyn-Williams, W. F. H. Ray, D. I. Rees, W. G. Rees, A. Reid, D. A. Robertson, F. J. Sale, T. H. Sellors, G. P. Thorold, R. L. Graves, M. N. Jackson, C. I. Pattullo, and A. D. K. Peters.

Pathology.—G. R. P. Aldred-Brown, E. N. Allott, H. N. Bradbrooke, A. V. Clemmey, P. F. Cluver, L. O. F. Fysh, T. C. Hunt, R. Lewthwaite, P. C. Mallam, M. J. W. Minshull, P. Morton, W. D. B. Read, D. A. Robertson, G. P. Roxburgh, J. de la Mare Savage, T. H. Sellors, C. W. Simpson, and R. S. Wordsworth.

Forensic Medicine and Public Health.—J. W. Alden, M. M. Baird, L. J. Barford, R. J. Brocklehurst, C. W. Carter, H. N. K. Elphick, K. J. Franklin, C. J. Fuller, J. R. B. Hern, P. H. Martin, J. D. Mills, H. W. Pearson, A. A. F. Peel, D. I. Rees, A. W. L. Row, T. E. Ryves, J. G. S. Thomas, E. C. Whitehall-Cooke, and G. P. Wright.

Medicine, Surgery, Midwifery.—G. R. P. Aldred-Brown, W. H. [illegible], W. H. Bradley, R. E. D. Cargill, C. W. Carter, S. H. Cattrall, J. L. Cox, C. L. Elgood, K. J. Franklin, A. T. [illegible], C. J. Fuller, D. R. Gawler, C. A. H. Green, F. H. [illegible], W. J. [illegible], H. W. Pearson, A. A. F. Peel, S. J. [illegible], I. M. [illegible], G. I. Wilson, and G. P. Wright.

UNIVERSITY OF DURHAM.—At the Convocation held on June 24th the following medical degrees were conferred :—

Doctor of Medicine.—Alan Angus, M.B., B.S., and Robert W. Locke, M.B., B.S.

Doctor of Medicine for Practitioners of 15 Years' Standing.—Henry H. R. Clarke, M.R.C.S., L.R.C.P.

Bachelor of Medicine and Bachelor of Surgery.—James R. Campbell, Oswald P. Chapman, Thomas L. J. Coxon, Ethel W. Daniels, Mary W. Dewell, George A. Gilmour, John C. Hall, Frances R. Henegan, M. Hopper, George E. Hyden, Ronald Keenlyside, Nora W. Kirk, John W. C. Leech, Thomas H. Meek, William Meikle, Thomas D. Miller, Guy Punshon, Margaret Ranken, James H. Saint, Margaret Scoresby-Jackson, Joseph A. Stobbs, Temperley Strother, Raymond L. Stubbs, and Edwin F. D. Walker.

Bachelor of Hygiene.—Margaret B. Herbst, M.B., B.S.

At the Convocation held on June 25th the following degrees were conferred :—

Doctor of Medicine.—Francis J. Benjamin, M.B., B.S., Roy N. Craig, M.B., B.S., Richard L. Dagger, M.B., B.S., William A. Jaques, M.B., B.S., and Thomas N. V. Potts, M.B., B.S., B.Hy., D.P.H.

Bachelor of Medicine and Bachelor of Surgery.—Thomas R. Aynsley, Elizabeth Bainbridge, William N. Booth, Joshua Carse, Stanislaus Curry, Archibald L. Fairlie, Thomas Fraser, James Henderson, Gordon C. Henry, John M. Johnson, Francis J. Lorriman, Kenneth V. Milburn, William C. Murray, John J. D. Naismith, Elsie L. Peet, John Reay, Matthew Ryle, Alfred Swindale, Geoffrey G. C. Taylor, and William A. Tweddle.

The following received the Diploma in Public Health (D.P.H.) :—

Margaret B. Herbst, M.B., B.S.

The following received the Diploma in Psychiatry (D.Psy.) :—

Reginald E. Illingworth, L.R.C.P. & S., L.F.P.S.G.

The following received the Licence in Dental Surgery (L.D.S.) :—

George A. Catcheside, James F. Coltman, M.B., B.S., Lionel G. Dewar, Wilton L. Milburn, Arthur T. Picton, and Alexander S. Robertson.

UNIVERSITY OF SHEFFIELD.—As a result of the recent final examinations for the degree of M.B., Ch.B., the following candidates were successful :—

With Honours (Class II.).—George E. Larks (with distinction in Gynæcology), Charles A. Lister, and Aaron S. Mushlin.

Ordinary.—Amy D. Baker, William F. L. Castle, George S. Davidson, Edward M. Dearn, Phyllis H. C. Eardley, Donald A. Grattan, Cornelia H. Greaves, Harry N. Green (distinction in Medicine), Edith Hatherley, Harold Kelson, John E. King, William W. Mathews, Herbert Mercer, John O. Schofield, and Bertrand R. Wallis.

Reginald E. Pleasance passed the examination for the M.D.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following were the successful candidates :—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—Robert L. Forsyth (passed on high marks), James E. McCauley, Ransome MacN. Allardyce, Annette K. Wood-Martin, Victor St. G. Vaughan, Richard G. Keays, Gilbert T. L. Archer, Barend P. Pienaar, Elspeth V. D. Hewat, Maiben A. W. Roberts, and Henry O. Clarke.

Part II., Medicine (M.B.).—Robert F. J. Henry (passed on high marks), Gordon Purdy, John K. S. Thompson, John L. Stuart, James S. Armstrong, John E. Beatty, Godfrey W. Garde, John R. Bradshaw, Edward Harvey, John Crawford, Charles J. du Plessis, John H. Bowyer, Leslie D. Dennard, Ralph A. Webner, Robert G. F. Thompson, Leslie M. Whitsitt, Gerrard A. Sloan, Alexander Hawthorne, Herbert W. Strong, Alfred J. Head, Lionel S. Levitt, and François J. Swanepoel.

Surgery (B.Ch.).—Gordon Purdy, John K. S. Thompson, Douglas L. Hemmingway, Maynard A. Gerrard, Robert E. Steen, Isidore Rosin, Desmond K. Lyons, John V. Morris, George A. Cowan, Alan J. Mooney, George Robinson, François J. Swanepoel, Carmichael Wilson, Leslie D. Dennard, Joseph Morris, John L. F. Steele, Otto G. Wilde, Eileen Braugan, Anthony B. Monks, Sylvia B. Wigoder, Gerrard A. Sloan, Simon Wigoder, Samuel McDermott, Mark J. Bradlaw, Samuel E. Magowen, Harry Ruben, Alexander L. Dobbyn, Kenneth F. Mackenzie, Richard L. G. Proctor, John H. Bowyer, James S. Armstrong, William A. Hopkins, Maurice D. Fox, Lionel S. Levitt, John N. Atkinson.

Midwifery (B.A.O.).—Thos. W. MacDowell (passed on high marks), John V. Morris, William Gallaugher, Wentworth A. Taylor, Thomas C. Foster, Robert V. Franklin, Richard T. Cronin, Annie T. Deane, Mary C. Livingston, William C. G. Potts, François J. Marais, Edward A. Bennet, William G. Maule, John St. Clair, Patrick Wallace, Harry Waters, William A. Hopkins, Oliver Chance, Edward C. Dudgeon, Robert H. McKeag, Gideon J. Joubert, Gerard A. A. Powell, Eric T. S. Rudd, Charles L. Taylor, Francis V. Duke, Caleb P. Wallace, David N. Power, Thomas G. B. Crawford, Margaret O'Neill, William O. Warrington, Edward S. A. Crawford, George F. Gillespie, Leslie D. Dennard.

tests are best done by the teacher, whom the children know and trust, rather than by the doctor, with whom they are apt to be shy. Children found wanting can be handed to the medical authority for more detailed examination. Deaf children could thus be discovered when treatment is of use and a large number of cases of deafness could thus be prevented. At present, these children go unrecognised, often until too late.

I may add that it is a matter of great gratification to me to find that the attention of otologists is becoming aroused to the necessity of prevention. I have been preaching it for the past 15 years, as has my friend Dr. Kerr Love in Scotland.

RESEARCHES ON LEPROSY AND THEIR BEARING ON THE TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—May I draw attention to a statement in Sir Leonard Rogers's lectures (THE LANCET, June 28th, p. 1297) in which he credits me with the statement that "the addition of 3 per cent. solutions of sodium gynocardate, morrhuate, or oleate to a pancreatic extract doubled the fat-splitting effect of the pancreatic lipase on an emulsion of olive oil." The accelerating action of sodium oleate on lipase varies considerably according to the percentage strength of the solutions used, and so far from using 3 per cent. strength solutions, 0·9 per cent. strength solutions were used in my experiments. My statement in the paper[1] referred to by Sir Leonard Rogers is "Systematic investigation of sodium oleate had previously shown that the accelerating action on extract of pancreas varies considerably according to the percentage strength of the solutions used; graduated amounts added to the extract show also a gradual rise in values up to a maximum, falling ultimately to nothing. I chose, therefore, a 0·9 per cent. solution of sodium oleate which had given good results formerly, and the same percentage solutions of sodium morrhuate and sodium gynocardate, using 1 and 2 c.cm. amounts of these solutions." Obviously the matter is of importance also in therapeutic dosage. He says further that these experiments in vitro led me to suggest a stimulating action of tissue lipolysis in part explanation of the therapeutic effect of sodium morrhuate and sodium gynocardate on acid-fast bacilli, and led him to investigate the possibility of these substances also stimulating the production of fat-splitting lipase in the blood of leprosy and tubercle cases, whereas, as a matter of fact, in my paper, after giving the actual results in my experiments *in vitro*, I went on to say that in view of the ascertained action of sodium oleate in vivo,[2] "it would seem reasonable to infer a direct stimulating action of tissue lipolysis in, at any rate, partial explanation of the therapeutic effect of sodium morrhuate and of sodium gynocardate, in addition to a direct destructive action claimed for both (Rogers) or for the chaulmoogrates alone (Walker and Sweeney) on acid-fast bacilli."

I am glad to see the confirmation of the lipase theory by Sir Leonard Rogers in the particular case of leprosy, which I have so long pointed out and maintained in cancer, tuberculosis, and other infectious diseases. I may, perhaps, be permitted to add that in 1912 I showed that in recovered tuberculosis the lipolytic activity of the serum is increased. Somewhat later it was found to be decreased in the acute stages, as well as (1914) in T.B. infected guinea-pigs and rabbits examined in the bacteriological laboratory, King's College. In my culture experiments also lipase killed tubercle bacilli.

I am, Sir, yours faithfully,
J. A. SHAW-MACKENZIE, M.D. Lond.
London, July 4th, 1924.

Obituary.

CHARLES HUNTER STEWART, D.Sc., M.B., C.M. EDIN.

BY the death of Dr. Charles Hunter Stewart, professor of public health and sanitary science and director of the John Usher Institute of Public Health, the University of Edinburgh has suffered another loss. Although he had been in poor health for some time, his death on June 30th at his residence in Melville-street, Edinburgh, came quite unexpectedly.

Prof. Stewart was born in Edinburgh in 1854, and educated at the University of his native city, while later he studied extensively on the continent. He first underwent training as a pharmaceutist, but, forsaking materia medica and chemical pharmacy, he applied himself with marked success to the study of experimental science and medicine, graduating Bachelor of Science in 1882, Bachelor of Medicine in 1884, and Doctor of Science in 1894. In 1880 he won the Hope Prize Scholarship in organic chemistry, and four years later the Mackay-Smith scholarship in chemistry. His early scientific training made him a keen observer and a most painstaking investigator. When in 1894 the University of Edinburgh decided to institute a public health laboratory in connexion with the chair of forensic medicine he was chosen by Sir Douglas Maclagan, then professor of medical jurisprudence, to organise and conduct the instruction in it. In 1898 he was appointed to the newly founded Bruce and John Usher Chair of Public Health, and he occupied that chair till his death. In 1902 he became also director of the Usher Institute of Public Health, to the planning and arranging of which he devoted a large amount of time and thought, the result being the provision of laboratories, which at that time were regarded as perhaps the finest in the country.

His colleague, Dr. J. Buchanan Young, writes: "In experiment Prof. Stewart was resourceful, and above all accurate, and he demanded the same accuracy in working from those whom he trained. As a young man he had worked hard, and he never failed to impress on his students the necessity for hard work if success was to be attained, and he took a keen interest in following the careers of those whom he had taught. His prolonged study in continental laboratories and his vast experience in laboratory work made him quick to appreciate improvements in processes and methods, but before any new methods were introduced into his courses of instruction they had to be thoroughly tested by himself as to accuracy of the results given. For many years he was well known and much sought after as an expert witness before the Scottish courts in river pollution cases, and in reference cases involving special knowledge of water-supply, &c. To the investigations connected with these he devoted a large amount of time and energy. The number of experiments he conducted, and the amount of labour and time he expended in satisfying himself as to the soundness of the views he expressed in evidence, were only known of by those who were associated with him in such work. His favourite reply when asked if it was absolutely necessary to make a certain experiment, which to the inquirer seemed somewhat troublesome, was 'Prove all things'! In later years he devoted himself largely to the epidemiological and statistical departments of public health. His grasp of figures was marvellous, and his memory for figures rather 'uncanny.' As a lecturer he was emphatic in style, interesting, and insistent on salient points. He had a quiet, somewhat 'pawky' humour, and those who met him in private life found in him a most interesting conversationalist, willing to discuss practically any subject. During 40 years as a teacher in the University (26 of these as professor of public health) he had seen many changes in the Edinburgh Medical School, and had taught a very large number of students. We who remain are all the poorer by his passing."

ondon Hospital.—The prizes and certificates ed by students of the London Hospital Medical College Dental School (University of London) were distributed Ionday, June 30th, by Sir Arthur Keith, in the Library he College. Lieut.-Colonel W. Marlborough Pryor, rman of the College Board, presided. Prof. William ght, the Dean, in his report stated that although the s 1914–18 were years of great difficulty for the College, could now confidently say that the difficulties had surmounted and that the College was never in a more nising or indeed more flourishing condition than it was resent. Among the changes which had taken place in the ege the most important was the discontinuance of the hing of what were formerly the subjects of study during first year of the medical curriculum—namely, elementary nistry, physics, and biology. Their action in this respect been recently followed by the General Medical Council, had removed elementary chemistry and physics from medical curriculum and made them the subjects of a medical examination. The change had provided them increased accommodation for the teaching of the purely lical subjects, while funds had been released for improving teaching arrangements in connexion with, more particu-y, the clinical subjects. The appointment of, in addition the staff of the medical unit, no fewer than five surgical four medical whole-time assistants, selected from the est of their younger men, was a new departure in the anisation of clinical teaching and should, with the ivalled clinical facilities which existed at the London spital, ensure that in the spheres of clinical teaching l research they would more than maintain their already h position among the medical schools of the country. The stees of the late Sir William Dunn had recently presented hospital, at a cost of £8000, with a series of clinical oratories, which would be officially opened in a few days. e Worshipful Company of Goldsmiths had given £15,000 the endowment of the Goldsmiths' Chair of Bacteriology. e number of students in attendance compared favourably h that of former years. In the academic year now closing y stood, he believed, alone among the larger medical ools in London and throughout the country in being e to report an increased entry—an increase due largely to entry of men from Oxford and Cambridge.

After presenting the prizes and certificates to the successful dents Sir Arthur Keith said that to get a good reputation s the easiest thing in the world, and with that object rything they did must be unselfish. The unforgivable which would never be forgotten was that of selfishness, t of playing entirely for one's own hand. In aid of a good utation came absolute honesty of purpose, speaking as r the truth as they could when the occasion called for it. ey should not mislead their patients. No medical man s honest who was not familiar with what was happening the best medical circles, in the way of discovery and advance medicine. They could not be honest unless they continued be medical students all through their lives. It was necessary them to read constantly the medical papers. The rticular kind of unselfishness which appealed to him re than any other was that which led men to devote their rgies and their time to the discovery of fresh facts which de medicine a better-equipped tool in the hands of medical ctitioners.

The following students were awarded prizes and certifi-tes:—

Price University Scholarship in Anatomy and Physiology—l 10s.: Mr. H. L. Green (University of Cambridge); £26 5s.: V. H. Brink, proxime accessit (University of Oxford). nical Medicine—£20 prize: Mr. E. V. Suckling; Honorary tificates: Mr. W. H. George, Mr. G. Milne, and Mr. G. King. nical Surgery—£20 prize: Mr. G. Milne; Honorary certifi-e: Mr. R. H. Wooderson. Clinical Obstetrics and Gynæcology £20 prize: Miss M. I. Neal; Honorary certificate: Mr. W. Thomas. Andrew Clark Prize in Clinical Medicine and thology—Biennial—£26: Mr. G. King; Honorary certificate: H. G. Wyatt. Letheby prizes in—(a) Organic Chemistry—5: Mr. A. M. A. Moore; (b) Chemical Pathology—£10: r. H. N. Bradbrooke; Honorary certificates in Anatomy and ysiology: Mr. D. H. Smith, Mr. F. H. N. Cruchley, and Mr. F. Ward. [illegible] prizes—(Elementary Clinical Surgery) £5 prizes: Mr. F. L. White, Mr. F. W. Tabois, Mr. S. Levy mpson, and Mr. H. L. Green. Honorary certificates: Mr. A. Taylor, Mr. R. K. Debenham, and Mr. R. J. Vince. inor Surgery)—£5 prizes: Mr. F. S. Duck, Mr. G. C. Dorling, r. D. R. W. Burbury and Mr. G. A. Coggin (divided), and r. A. M. A. Moore. Honorary certificates: Mr. F. H. N. uchley, Mr. H. A. Eason, Mr. E. N. Callum, Mr. W. D. Williams, d Mr. C. Wall. Practical Anatomy—£1 4s. prize: Mr. L. son: £2 2s. prizes: Mr. W. D. Williams, Mr. A. F. Parker, d Mr. H. A. Eason. Anderson prizes in Elementary Clinical edicine—£5 prizes: Miss C. M. Hext and Mr. H. N. Bradbrooke. norary certificates: Mr. S. Howard, Mr. W. E. Parry, Mr. Morton, Miss L. G. Apps, Mr. V. H. Brink, Mr. A. C. Gairdner, r. H. M. Bates, Mr. J. H. Ripka, Mr. E. W. Hayward, and r. H. M. Lloyd. Arnold Thompson Prize in Diseases of Children £15 prize: Mr. G. Kin [illegible] orary certificate: Mr. W. A. [illegible] Harold [illegible] erative Dental Surgery— Mr. W. R. [illegible] Mr. M. Spelber (divided).

Honorary certificate: Mr. D. W. N. Squires. The London Prize in Dental Surgery and Pathology—£5 5s.: Mr. D. W. N. Squires. The London Prize in Dental Prosthetics—£5 5s.: Mr. O. N. Catchpole; Honorary certificate: Mr. I. Frankel. Class examination prizes (each of the value of £3 3s.)—Dental Surgery and Pathology: Mr. J. L. Gordon; Honorary certificate: Mr. B. J. Swyer. Dental Prosthetics: Mr. O. N. Catchpole; Honorary certificates: Mr. H. W. Duchesne, Mr. J. E. M. Hennessey, Mr. J. N. Noriskin, Mr. A. Schultz, Mr. A. Silva-Jones, and Mr. A. Bendelstein. Dental Metallurgy: Mr. J. W. Gilbert. Dental Histology (Normal): Mr. H. Middleburgh; Honorary certificate: Mr. G. R. Mears. Dental Anatomy: Mr. H. Middleburgh.

Society of Apothecaries of London.—On July 8th a dinner was given by the Society (in their hall) to representatives of the medical profession from the Dominions. The guests were received by the Master, Dr. Thomas Wakefield, and the Wardens, Dr. A. D. Brenchley and Dr. T. V. Dickinson. In proposing the toast of "Our Guests," Dr. Wakefield gave an interesting sketch of the history of the Society of Apothecaries from its foundation in the reign of James I. He compared the growth of the colonies at different periods of the Society's life, and said that he regarded this evening as one of the most important events in its whole history. Lieut.-Colonel Grant, I.M.S., replied for India and referred to the work of Sir Ronald Ross and Sir Leonard Rogers; Dr. T. J. Costello responded eloquently on behalf of Canada. Dr. T. Taylor Downie, speaking for Australia, said that their greatest drawback in that continent was lack of population, and referred to it as a land of splendid endeavour. For New Zealand Dr. Arnold Izard spoke, and for South Africa Dr. H. Temple Mursell. Newfoundland was represented by Dr. T. W. Grenfell, who said that he ought really to represent Labrador, and gave a vivid account of life and work in that country. Other speakers were Sir Bruce Bruce-Porter, vice-chairman of the Dominions Hospitality Committee, Dr. Gordon Brown, senior Past Master of the Society, Sir Ronald Ross, and Dr. A. L. Hoops. Among the guests were Sir William Hale-White, Dr. Herbert Spencer, Sir W. J. Collins, Mr. A. Mortimer Woolf, Mr. E. T. C. Milligan, Sir George Buchanan, Dr. A. J. S. Brandon, Dr. F. W. B. Greaves, Colonel E. C. Freeman, Dr. J. J. Holland, Dr. E. Fyffe, and Dr. W. F. Burfitt. At the conclusion of the evening an illustrated booklet descriptive of the Society's hall and of the "Art and Mistery" of the apothecaries was presented to each guest.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, July 15th.

SPECIAL GENERAL MEETING OF FELLOWS: at 5 P.M., to be immediately followed by a
GENERAL MEETING OF FELLOWS:
Ballot for election to the Fellowship.

LONDON DERMATOLOGICAL SOCIETY.
Wednesday, July 16th.—4.30 P.M., Annual General Meeting at St. John's Hospital, Leicester-square.
Clinical Cases and Pathological Specimens will be shown.
The Monthly Dinner of Fellows will not take place on this occasion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Monday, July 14th.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Mr. Simson: Diseases of Women. 2 P.M., Mr. Bishop Harman: Eye Dept.
Tuesday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
Wednesday.—11 A.M., Medical Registrar: Medical Wards. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Medical Registrar: Clinical Methods. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
Friday.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.
Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.
Thursday, July 17th.—5 P.M., Mr. Richard Lake: Otosclerosis. (Geoffrey E. Duveen Lectures in Otology.)

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-street, W.C.
Thursday, July 17th.—4 P.M., Dr. Pearson: Pyrexia of Obscure Origin.

Diploma in Public Health.

Part I., Chemistry, Bacteriology, Physics, and Meteorology.—Alice M. A. Downing, William E. Hutchinson, and Edward Parker.

Part II., Sanitary Engineering; Practical Sanitary Report; Hygiene and Epidemiology; Vital Statistics and Public Health Law.—Benjamin W. D. Fayle, William E. Hutchinson, Alice M.A. Downing, Robert S. McElroy, Alfred E. Campbell, Mary M. Galvin, Ruth Lemon, Ninian McI. Falkiner, and Iris P. Nelis.

Diploma in Gynæcology and Obstetrics.

Sylvia Gytha de Lancey Chapman.

Royal College of Physicians of London.—An extraordinary Comitia was held on July 3rd, Sir Humphry Rolleston, the President, occupying the chair. A report was received from the Treasurer on the Commemoration of the Tercentenary of the death of Thomas Sydenham at the Académie de Médecine de Paris, held on May 20th last. The quarterly report of the College Finance Committee was received and adopted. Prof. A. J. Hall was reappointed a representative of the College on the Court of Governors of the University of Sheffield.

Royal College of Surgeons of England.—The annual meeting of the Fellows of the College was held at 10 A.M. on July 3rd for the election of three Fellows into the Council, in the vacancies caused by the retirement in rotation of Mr. W. E. Haslam, Mr. T. H. Openshaw, and Mr. Raymond Johnson. The President of the College, Sir John Bland-Sutton, was in the chair. The voting was carried out mainly by post, as has been the custom for many years, 1140 voting-papers being thus received from all parts of the world, while eight Fellows voted in person. There were 11 candidates for the three vacancies, and as the result of the ballot the President declared the following Fellows to be elected: William McAdam Eccles with 463 votes, Wilfred Trotter with 371 votes, and Sir Charles Gordon-Watson with 359 votes.

In the afternoon of the same day a reception was held by the President and the Council in the museum of the College, when the annual exhibitions of additions to the museum was opened for inspection between 4 and 6 P.M. Many specimens of surgical, pathological, and anthropological interest were on show, and of the additions to the museum some account was given in The Lancet of last week (p. 28). The guests were received by the President and Lady Bland-Sutton, and for the first time in the history of the College, ladies were amongst those invited. Mr. H. J. Waring, Vice-President of the College, was also receiving; Sir Berkeley Moynihan, Vice-President, was unavoidably absent. The guests included all the members of the Council of the Royal College of Surgeons and ladies, Lord and Lady Riddell, Sir Rickman and Lady Godlee, Mr. and Mrs. Stanley Baldwin, Lord and Lady Aberconway, Sir Edward and Lady Boyle, Sir George and Lady Frampton, Lady Evans, Mr. and Mrs. Massey-Lyon, Colonel A. Sankey, and Mr. and Mrs. Gwynne. A programme of music was given by the Keith Prowse orchestra, and refreshments were served in the Inner Hall.

Beit Memorial Fellowship.—At a recent meeting of the trustees of the Beit Memorial Fellowship for Medical Research, Sir James K. Fowler, the hon. secretary, presented the annual report. The report stated that as far as the trust was concerned, the work of research had been carried on during the past year by one Senior Fellow, one fourth year Fellow, and 20 Junior Fellows, and the reports of the directors of the laboratories in which they were engaged indicated that in all cases their work had been satisfactory, and in many cases contained the statement that valuable additions to science might result from the researches upon which they were engaged. The Advisory Board have recommended that all the Junior Fellowships which do not now expire should be renewed for a further period of one year. Each year of late, Sir James Fowler said, as the number of candidates whom it was possible to exclude by a preliminary examination has diminished, the task of selection has become more difficult, and it can be stated that on this occasion every candidate gave evidence of being either actually engaged in scientific work or of capacity to undertake it. Eighty-six applications for forms and information were received in response to the advertisements announcing the election now to be held. Two of the Junior Fellows, Dr. Robert K. Cannan and Miss Ethel M. Luce, who had applied for an extension of their Fellowship to a fourth year, had withdrawn their applications owing to their appointment to Rockefeller Travelling Scholarships, as both Fellowships could not be held at the same time. This arrangement had the advantage of enabling such of the Beit Fellows as had shown exceptional capacity for research to obtain the great advantage of working for a time in laboratories in the United States, and did not prevent them from subsequently holding a Senior Fellowship on the Beit Foundation. Dr. Thomas Renton Elliott was appointed assistant hon. secretary. H. Davenport Kay, a Junior Fellow, was appointed to a Fourth Year Fellowship. The following are the names of the candidates elected to Junior Fellowships with an indication of the direction of research or proposed research. Alan Sterling Parkes, Ph.D., the physiology of reproduction. Henry Cohen, (1) continuation of work on composition of cerebrospinal fluid; (2) practical application of the "meningitis law."; (3) rate and cause of disappearance of glucose in the G.C.S.F. in meningitis; (4) effect of alterations in the chemistry of the blood or the permeability of the choroid plexus. Honor Bridget Fell, B.Sc., (1) experimental study of the nature of tumour growth. Margaret Averil Boas, B.Sc., action of anti-rachitic vitamin in diet and of light radiation in promoting retention of calcium and phosphorus. Henry Francis Holden, M.A., study of optically active substances, other than glucose, in normal and diabetic protein-free blood filtrates.

Rockefeller Medical Fellowships.—The Medical Research Council announce that they have awarded Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1924–25, to the following: Robert Keith Cannan, M.Sc. Lond., Senior Assistant in Biochemistry, University College, London; John Josias Conybeare, D.M. Oxf., M.R.C.P. Lond., Assistant Physician and Warden of the College at Guy's Hospital, London; James Rögnvald Learmonth, M.B., Ch.B.Glasg., Assistant to the Professor of Surgery, Anderson College of Medicine, Glasgow; Ethel Marjory Luce, M.D. T.C. Dub., Lister Institute of Preventive Medicine, London; John William McNee, D.S.O., D.Sc., M.D.Glasg., M.R.C.P. Lond., Senior Assistant in the Medical Unit, University College Hospital, London; William Robson, B.Sc. Lond., Chemical Assistant in the Department of Therapeutics, University of Edinburgh.

Society of Medical Officers of Health.—Owing to the illness of Dr. T. W. Naylor Barlow, the annual provincial meeting of this society will not be held at Wallasey on July 14th as arranged. A short business meeting to deal with matters on the agenda for the annual provincial meeting will be held at 2.30 P.M., on July 18th, at the University of Liverpool.

Medical Women's International Association.—A meeting of this Association will be held in London from July 14th to 21st, at the invitation of the British Medical Women's Federation. On July 15th and 16th council and general meetings of the Association will be held, and on July 17th a discussion on Maternal Morbidity will take place. Various hospitals will be visited in London and Brighton. The social arrangements include a reception on the evening of July 16th at 10, Downing-street, by the Prime Minister, who, with other Members of Parliament, will also entertain members to tea at the House of Commons the following afternoon. A dinner, by invitation of the British Medical Women's Federation, will be held at the Trocadero Restaurant, London, W., on July 17th. Further particulars of the Congress can be obtained from the hon. secretary of the Hospitality Committee, Dr. K. F. Lander, 49, Albany-street, London, N.W. 1.

London Ambulance Service.—In a report presented to the London County Council by the Fire Brigade Committee, attention is drawn to a suggestion made in the recent report of the Ambulance Cases Disposal Committee, which was not included in the Committee's final recommendations. About 14 per cent. of the total number of cases dealt with by the ambulance service in the year 1922–23 were in respect of the removal of patients from one institution to another after the administration of emergency treatment. This arrangement involves the withdrawal of ambulances from the more pressing service of attending upon street accidents, and the Ambulance Committee suggested that a simpler and less costly type of ambulance might be used for this subsidiary purpose. The Fire Brigade Committee state that they have under consideration the practicability of this suggestion, although they hope that, if effect be given to the recommendations of the Ambulance Committee, the necessity for such transfers will be considerably lessened, if not entirely dispensed with. The London County Council this week passed a resolution to the effect that no institution which is not equipped for the reception and treatment of serious cases of accident or illness be retained on the list of institutions to which ambulance cases shall, in the first instance, be taken, that a list of such institutions be prepared, and that the coöperation of the Ministry of Health be sought in the case of infirmaries, and of King Edward's Hospital Fund in the case of hospitals. This resolution embodies the substance of two of the recommendations of the Ambulance Committee. The Fire Brigade Committee will settle the list.

Expenditure on Vaccination.

Mr. BLACK asked the Minister of Health whether he could supply details of the expenditure on vaccination for the year 1921–22, stated to amount to £172,558: and how many infants were actually vaccinated for this sum, and what the cost per infant vaccinated had been.—Mr. WHEATLEY replied: The sum of £172,558 included £10.158 paid to public vaccinators out of the Exchequer contribution accounts of the local authorities and £162,400 expended by boards of guardians out of the rates, but I am unable to supply any further details. The number of infants vaccinated by public vaccinators during the year ended Sept. 30th, 1922, was 205,106. It is not possible to state the cost per infant vaccinated, as the expenditure on public vaccination includes also the cost of other vaccinations and revaccinations, and the necessary administrative expenditure under the Vaccination Acts.

Child Assault in Scotland.

The DUCHESS of ATHOLL asked the Secretary for Scotland whether, in view of the numerous serious cases of child assault occurring in Scotland, he would set up a committee of inquiry to inquire into the extent of this evil and to suggest how it might be remedied.—Mr. STEWART (Under-Secretary for Health for Scotland) replied: My right hon. friend is not satisfied that the circumstances in Scotland are such as to justify the expectation that an inquiry of the nature indicated in the question would serve a useful purpose. If, however, the noble lady will favour him with a statement of the grounds on which her suggestion is based, he is prepared to give the matter further consideration.

THURSDAY, JULY 3RD.

Tuberculous Persons in Sanatoriums.

Mr. ROBERT MORRISON asked the Minister of Health whether he has any information as to the number of tuberculous persons at present in sanatoriums and the number awaiting admission.—Mr. WHEATLEY replied: The number of persons receiving treatment in residential institutions under the tuberculosis schemes of local authorities in England and Wales on June 1st last was 18,245 and the number of persons recommended for and awaiting such treatment on that date was 4150. I am hopeful that the circular issued by my department in February last promising grants in aid of approved proposals for the development of the health services will result in a substantial addition to the available accommodation for the treatment of this disease.

Criminal Statistics for 1922.

Mrs. WINTRINGHAM asked the Home Secretary if he would give information as to the date when the publication of the criminal statistics for 1922 might be expected in view of the lapse of time since the report for 1921 was issued; and whether copies of the criminal statistics would be circulated officially to all benches of magistrates in addition to the circulation of official copies to all police authorities.—Mr. HENDERSON replied: It is hoped that the volume will be issued early next month. Copies are supplied officially to all superior criminal courts, including recorders and chairmen of quarter sessions, but I am afraid it is not possible to make a free issue to all benches of magistrates.

TUESDAY, JULY 8TH.

Notified Diseases.

In reply to a question how many cases of the following diseases have been notified this year—small-pox, diphtheria, scarlet fever, pneumonia, enteric fever, encephalitis lethargica, Mr. WHEATLEY (Minister of Health) replied: The numbers of cases of these diseases notified (uncorrected figures) during the 26 weeks ended June 28th, 1924, are as follows: Small-pox, 2196; diphtheria, 18,095; scarlet fever, 36,910; pneumonia, 41,321; enteric fever, 1683; encephalitis lethargica, 3620.

Sickness Benefit Delays.

Mr. SAMUEL ROBERTS asked the Minister of Health whether he was aware of complaints arising from delay in payment of sickness benefit under the National Health Insurance Act to sick insured persons; and, if so, whether he would appoint a departmental committee to inquire into the matter.—Mr. GREENWOOD (Parliamentary Secretary to the Minister of Health) replied: My right hon. friend is aware that complaints are occasionally made of delay in the payment of benefit to which insured persons are entitled. The subject has been and is being dealt with departmentally and he does not think it necessary to appoint a departmental committee, particularly in view of the appointment of a Royal Commission to review the whole system of national health insurance.

Free Use of Public Baths.

Mr. AYLES asked the Minister of Health whether, in view of the serious difficulty arising out of the overcrowding of the people in the large towns, he could see his way to advise local authorities that if in their opinion it was necessary to public health for unemployed persons and their dependents to have the free use of the public baths in their areas, he was prepared favourably to consider grants in aid for that purpose.—Mr. GREENWOOD replied: My right hon. friend regrets that he has no funds available for this purpose.

Coöperation in Town Planning.

Mr. AYLES asked the Minister of Health how many areas had passed the necessary resolutions preliminary to making town plans for their area; and whether he would see that the closest coöperation was advised between town planning, housing, and sanitary and improvement committees in order to avoid conflicting policies and overlapping in the alteration of developed areas and the layout of new ones.—Mr. GREENWOOD replied: Resolutions have been passed by 229 local authorities. My department are constantly emphasising the importance of the closest coöperation not only between different committees of the local authority but also with outside interests.

Inquiry into Final Awards.

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Pensions if he had received a resolution from the Nottingham and district war pensions committee, in which they urged him to review the whole system of final awards, on the grounds that the present system involved undue hardship and even injustice in many cases; and whether, in view of the number of unsuccessful appeals and the dissatisfaction existing among the appellants at their treatment, he would cause the whole system to be inquired into.—Mr. J. W. MUIR replied: My right hon. friend has not yet received the resolution referred to. I may, however, remind the noble lord that my right hon. friend has, as indicated in his reply to the hon. and gallant Member for East Rhondda on March 27th last, put in operation arrangements which will enable cases in which an award is found to have been erroneously declared final to be amended.

Medical Examination and Home Treatment.

Mr. GROVES asked the Minister of Pensions whether he had considered the effect upon ex-Service men of Circular M.P.A.O. 15A, home treatment, which in cases where, as a result of medical examination by the Ministry doctors, treatment by a general practitioner was necessary, advised consultation with the national health insurance doctor on whose panel the man was listed, but also stated that the man would not be prevented from working at a remunerative occupation in consequence of and during treatment allowance therefore not being payable; whether he was aware of the cases where the panel doctors thus concerned, after careful examination, had issued certificates definitely stating that they found the man incapable of work, but the Ministry of Pensions had refused to honour such certificate; and whether, when such decision was given for disabilities which the Ministry agreed as being due to or aggravated by war service, he would give instructions to local area offices that certificates granted by the national health insurance doctor, to whom the man was specially referred, were acceptable and full treatment allowances be granted for the periods of incapacity covered.—Mr. J. W. MUIR replied: The conditions governing the grant of allowances under Article 6 of the warrant are not identical with those which determine certification for the purpose of sickness benefit under the National Health Insurance Acts. My right hon. friend regrets, therefore, that he is unable to adopt the suggestion in the last part of the question. At the same time, the circular letter referred to does not appear to my right hon. friend to be altogether satisfactory, and it will be reconsidered.

MEAT INSPECTION IN SCOTLAND.—The Scottish Board of Health have issued to all local authorities in Scotland revised regulations, which come into force on August 1st, dealing with the inspection of meat and kindred matters. The object of the regulations is to protect consumers from diseased or unsound meat. In a covering circular the Board explain that the new regulations (the official title of which is "The Public Health (Meat) Regulations (Scotland), 1924") cover practically the same scope as the Meat Inspection Regulations issued in April, 1923, with some adjustments designed to improve the machinery of administration and with some additions. Among the matters the machinery for dealing with which has been adjusted are the inspection of the carcasses of animals slaughtered because of accident or for other emergency reasons, and the hawking of meat and meat-food products from carts or other vehicles or from barrows, baskets, booths or stances, and among the new provisions is one prohibiting the hanging of carcasses intended for purposes of food in stables and similar places, the carrying on of a butcher's business in premises used as living accommodation, and the storing of meat intended for sale in living and sleeping rooms. Copies of the regulations can be obtained from H.M. Stationery Office, 120, George-st., Edinburgh, price 4d.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 8TH.

Liquor (Popular Control) Bill.

THE debate was concluded on Lord Banbury's motion for the rejection of the Bishop of Oxford's Liquor (Popular Control) Bill.

The motion for rejection was carried by 166 votes to 50, majority 116.

HOUSE OF COMMONS.

WEDNESDAY, JULY 2ND.

Legacies to Hospitals.

THE Finance Bill was considered in Committee, Mr. YOUNG, Chairman of Committees, in the chair.

Viscount EDNAM moved a new clause to provide that legacy and succession duty should not be leviable on testamentary bequests made to hospitals carried on in the public interest. He said that the dividends on bequests and legacies were the only regular source of income on which the hospitals could rely. The cost of the concession, it was calculated, would be between £80,000 and £130,000 a year.

Lieut.-Colonel FREMANTLE said that hospitals were an absolute necessity of modern civilisation, and if charitable efforts were to fail there was not the least question that there would be an overwhelming demand that the hospitals should be maintained and extended out of the rates and taxes.

Sir C. BARRIE, speaking as the past chairman of one of the largest hospitals in Scotland, supported the appeal, and said that it would be lamentable if the country were to allow its hospitals to be put on the rates or kept up by money provided by the State.

Mr. SNOWDEN, Chancellor of the Exchequer, said that if they were discussing this question as a sentimental matter they would be all agreed; but they must not allow their sentiments to blind them to reasonable arguments. This proposal really amounted to a State subsidy to the voluntary hospitals and the money would be handed over without any control as to the spending of it. Moreover, if the concession were granted, the case would be irresistible for its extension to other charities. He was not going to say that it was inadvisable that the State should make a contribution to the voluntary hospitals, but if that were done this was not a desirable way of doing it. If legacies to hospitals were freed from duty he did not think that the hospitals would gain very much and the State would lose about £200,000 a year. He was therefore compelled to resist the amendment.

On a division the proposed new clause was negatived by 251 votes to 148, majority against 103.

Ratio of Births and Deaths in Great Britain.

Mr. BLACK asked the Minister of Health whether he would state the extreme variations of the rates of births and deaths in the various localities in Great Britain, and also the average rate of births and deaths for the whole country during the past year.—Mr. WHEATLEY replied: In England and Wales during 1923 the birth- and death-rates per 1000 population ranged in various types of administrative area, are as follows:—

	Births from—	Deaths from—
Urban areas—		
50,000 population and over ..	13·0 to 27·5 ..	9·0 to 16·3
20,000 to 50,000 population ..	11·0 to 31·4 ..	7·2 to 16·5
Under 20,000 (ignoring populations of less than 1000) . ..	7·2 to 35·4 ..	4·8 to 20·5
Rural areas—		
Ignoring populations of less than 1000	9·8 to 34·7 ..	7·0 to 19·7

The average rates for England and Wales are: Births, 19·7; deaths, 11·6. As regards the figures for Scotland, the hon. Member will no doubt address a question to the Secretary for Scotland.

Officers' Disability Retired Pay.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty whether he was aware that disabled officers who retired under the special terms laid down in A.F.O. 1358/1922 were not considered by the Ministry of Pensions to be eligible for disablement pensions, on the ground that they had received special treatment by the Admiralty; and whether the 5½ per cent. reduction in retired pay would be applicable to these officers.—Mr. HODGES replied: I am aware that the Ministry of Pensions does not regard officers retired upon the special terms granted in 1922 for the purpose of clearing the lists as eligible for disability retired pay under its regulations. As regards the second part of the question, the special rates of retired pay sanctioned in 1922 are subject to the 5½ per cent. reduction except in certain cases of young officers who were given the right to commute the whole of their retired pay.

Final Awards of Ex-Service Men.

Mr. WILLIAM ALBERT JENKINS asked the Minister of Pensions if he was aware that certain concessions had recently been made with regard to the final awards of ex-Service men; and, as a large number of ex-Service men were, on account of technicalities, experiencing much difficulty in getting their cases properly inquired into and were suffering injustice, would he take steps to repeal the Final Awards Act.—Mr. J. W. MUIR (Parliamentary Secretary to the Ministry of Pensions) replied: General instructions providing for an improved procedure for the correction of awards which are found to have been erroneously declared final have only been issued within the last few weeks, and further experience is, in the opinion of my right hon. friend, necessary before it can be determined that any modification of them is required.

Uniform Standard of Health Services.

Mr. BLACK asked the Minister of Health whether he would set up a committee to inquire into the necessity for, and the advantages of establishing, a minimum standard in the administration of all health services included in his Ministry in order to secure that the health interests of the public should be conserved in areas where the local authorities might not be progressive; and whether he would include expert medical officers of health upon such a committee.—Mr. WHEATLEY replied: As at present advised, I do not think the appointment of such a committee would be of advantage.

Royal Commission on Lunacy.

Mr. COSTELLO asked the Minister of Health if he would say whether the terms of reference to the Royal Commission on Lunacy included an inquiry into the conditions which obtain in mental institutions of every kind and the present régime to which the inmates were subject; and whether provision would be made for defraying the expenses incurred by witnesses in coming and staying in London to attend the sittings of the Commission.—Mr. WHEATLEY replied: The terms of reference of the Royal Commission include an inquiry into the certification, detention, and care of persons under the Lunacy Acts whether in public or private institutions or in single care. Witnesses summoned by the Commission to give evidence before them in London will be repaid their expenses in accordance with the scale prescribed by the Treasury.

Poplar Report on Food Adulteration.

Mr. LINFIELD asked the Minister of Health whether his attention had been called to the report on food adulteration by Mr. A. E. Parkes, the borough analyst for Poplar; and whether he could hasten the report of the Government Committee so that early action might be taken.—Mr. WHEATLEY replied: Yes, Sir, my attention has been called to the Poplar borough analyst's report. I understand that the Committee hope to present their report in the near future.

Overcrowding in Shoreditch.

Mr. THURTLE asked the Minister of Health whether he was aware of the fact that there were dwelling-houses in Essex-street, Shoreditch, in which the average number of occupants per room exceeded five; and if, in view of the moral and social consequences of such overcrowding, he was prepared to take power to acquire some of the large number of empty houses in the Sloane-square neighbourhood in order to provide better accommodation for the people.—Mr. WHEATLEY replied: I am aware of the overcrowded conditions in Central London. Local authorities have power to acquire and adapt large empty houses, but experience has shown that this is not usually the most economical means of providing fresh accommodation. I am satisfied that the best remedy for overcrowding is the building of new houses.

Housing Bill and Larger Houses.

Mr. TREVELYAN THOMSON asked the Minister of Health if he was aware that since the introduction of his Housing Bill the representatives of over 300 local authorities, representing the chief cities and towns in the country, assembled in conferences at Newcastle-on-Tyne, Manchester, Sheffield, London, Bristol, and Cardiff, had in all cases unanimously passed resolutions protesting against the subsidy being limited to the small type of houses named in his Bill; and, in view of this unanimous feeling in favour of a larger house, would he take powers which would enable him to grant the subsidy to houses of an additional 100 superficial feet on the recommendation of the local authorities concerned.—Mr. WHEATLEY replied: I cannot accept the suggestion that local authorities are unanimously in favour of an extension of the subsidy to larger houses, and I do not propose to ask the House to review the decision which it has already taken in regard to the size of the houses.

Expenditure on Vaccination.

Mr. BLACK asked the Minister of Health whether he could supply details of the expenditure on vaccination for the year 1921–22, stated to amount to £172.558; and how many infants were actually vaccinated for this sum, and what the cost per infant vaccinated had been.—Mr. WHEATLEY replied: The sum of £172.558 included £10.158 paid to public vaccinators out of the Exchequer contribution accounts of the local authorities and £162,400 expended by boards of guardians out of the rates, but I am unable to supply any further details. The number of infants vaccinated by public vaccinators during the year ended Sept. 30th, 1922, was 205,106. It is not possible to state the cost per infant vaccinated, as the expenditure on public vaccination includes also the cost of other vaccinations and revaccinations, and the necessary administrative expenditure under the Vaccination Acts.

Child Assault in Scotland.

The DUCHESS OF ATHOLL asked the Secretary for Scotland whether, in view of the numerous serious cases of child assault occurring in Scotland, he would set up a committee of inquiry to inquire into the extent of this evil and to suggest how it might be remedied.—Mr. STEWART (Under-Secretary for Health for Scotland) replied: My right hon. friend is not satisfied that the circumstances in Scotland are such as to justify the expectation that an inquiry of the nature indicated in the question would serve a useful purpose. If, however, the noble lady will favour him with a statement of the grounds on which her suggestion is based, he is prepared to give the matter further consideration.

THURSDAY, JULY 3RD.

Tuberculous Persons in Sanatoriums.

Mr. ROBERT MORRISON asked the Minister of Health whether he has any information as to the number of tuberculous persons at present in sanatoriums and the number awaiting admission.—Mr. WHEATLEY replied: The number of persons receiving treatment in residential institutions under the tuberculosis schemes of local authorities in England and Wales on June 1st last was 18,245 and the number of persons recommended for and awaiting such treatment on that date was 4150. I am hopeful that the circular issued by my department in February last promising grants in aid of approved proposals for the development of the health services will result in a substantial addition to the available accommodation for the treatment of this disease.

Criminal Statistics for 1922.

Mrs. WINTRINGHAM asked the Home Secretary if he would give information as to the date when the publication of the criminal statistics for 1922 might be expected in view of the lapse of time since the report for 1921 was issued; and whether copies of the criminal statistics would be circulated officially to all benches of magistrates in addition to the circulation of official copies to all police authorities.—Mr. HENDERSON replied: It is hoped that the volume will be issued early next month. Copies are supplied officially to all superior criminal courts, including recorders and chairmen of quarter sessions, but I am afraid it is not possible to make a free issue to all benches of magistrates.

TUESDAY, JULY 8TH.

Notified Diseases.

In reply to a question how many cases of the following diseases have been notified this year—small-pox, diphtheria, scarlet fever, pneumonia, enteric fever, encephalitis lethargica, Mr. WHEATLEY (Minister of Health) replied: The numbers of cases of these diseases notified (uncorrected figures) during the 26 weeks ended June 28th, 1924, are as follows: Small-pox, 2106; diphtheria, 18,095; scarlet fever, 36,910; pneumonia, 41,321; enteric fever, 1683; encephalitis lethargica, 3020.

Sickness Benefit Delays.

Mr. SAMUEL ROBERTS asked the Minister of Health whether he was aware of complaints arising from delay in payment of sickness benefit under the National Health Insurance Act to sick insured persons; and, if so, whether he would appoint a departmental committee to inquire into the matter.—Mr. GREENWOOD (Parliamentary Secretary to the Minister of Health) replied: My right hon. friend is aware that complaints are occasionally made of delay in the payment of benefit to which insured persons are entitled. The subject has been and is being dealt with departmentally and he does not think it necessary to appoint a departmental committee, particularly in view of the appointment of a Royal Commission to review the whole system of national health insurance.

Free Use of Public Baths.

Mr. AYLES asked the Minister of Health whether, in view of the serious difficulty arising out of the overcrowding of the people in the large towns, he could see his way to advise local authorities that if in their opinion it was necessary to public health for unemployed persons and their dependents to have the free use of the public baths in their areas, he was prepared favourably to consider grants in aid for that purpose.—Mr. GREENWOOD replied: My right hon. friend regrets that he has no funds available for this purpose.

Coöperation in Town Planning.

Mr. AYLES asked the Minister of Health how many areas had passed the necessary resolutions preliminary to making town plans for their area; and whether he would see that the closest coöperation was advised between town planning, housing, and sanitary and improvement committees in order to avoid conflicting policies and overlapping in the alteration of developed areas and the layout of new ones.—Mr. GREENWOOD replied: Resolutions have been passed by 229 local authorities. My department are constantly emphasising the importance of the closest coöperation not only between different committees of the local authority but also with outside interests.

Inquiry into Final Awards.

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Pensions if he had received a resolution from the Nottingham and district war pensions committee, in which they urged him to review the whole system of final awards, on the grounds that the present system involved undue hardship and even injustice in many cases; and whether, in view of the number of unsuccessful appeals and the dissatisfaction existing among the appellants at their treatment, he would cause the whole system to be inquired into.—Mr. J. W. MUIR replied: My right hon. friend has not yet received the resolution referred to. I may, however, remind the noble lord that my right hon. friend has, as indicated in his reply to the hon. and gallant Member for East Rhondda on March 27th last, put in operation arrangements which will enable cases in which an award is found to have been erroneously declared final to be amended.

Medical Examination and Home Treatment.

Mr. GROVES asked the Minister of Pensions whether he had considered the effect upon ex-Service men of Circular M.P.A.O. 15A, home treatment, which in cases where, as a result of medical examination by the Ministry doctors, treatment by a general practitioner was necessary, advised consultation with the national health insurance doctor on whose panel the man was listed, but also stated that the man would not be prevented from working at a remunerative occupation in consequence of and during treatment allowance therefore not being payable: whether he was aware of the cases where the panel doctors thus concerned, after careful examination, had issued certificates definitely stating that they found the man incapable of work, but the Ministry of Pensions had refused to honour such certificate; and whether, when such decision was given for disabilities which the Ministry agreed as being due to or aggravated by war service, he would give instructions to local area offices that certificates granted by the national health insurance doctor, to whom the man was specially referred, were acceptable and full treatment allowances be granted for the periods of incapacity covered.—Mr. J. W. MUIR replied: The conditions governing the grant of allowances under Article 6 of the warrant are not identical with those which determine certification for the purpose of sickness benefit under the National Health Insurance Acts. My right hon. friend regrets, therefore, that he is unable to adopt the suggestion in the last part of the question. At the same time, the circular letter referred to does not appear to my right hon. friend to be altogether satisfactory, and it will be reconsidered.

MEAT INSPECTION IN SCOTLAND.—The Scottish Board of Health have issued to all local authorities in Scotland revised regulations, which come into force on August 1st, dealing with the inspection of meat and kindred matters. The object of the regulations is to protect consumers from diseased or unsound meat. In a covering circular the Board explain that the new regulations (the official title of which is "The Public Health (Meat) Regulations (Scotland), 1924") cover practically the same scope as the Meat Inspection Regulations issued in April, 1923, with some adjustments designed to improve the machinery of administration and with some additions. Among the matters the machinery for dealing with which has been adjusted are the inspection of the carcases of animals slaughtered because of accident or for other emergency reasons, and the hawking of meat and meat-food products from carts or other vehicles or from barrows, baskets, booths or stances, and among the new provisions is one prohibiting the hanging of carcasses intended for purposes of food in stables and similar places, the carrying on of a butcher's business in premises used as living accommodation, and the storing of meat intended for sale in living and sleeping rooms. Copies of the regulations can be obtained from H.M. Stationery Office, 120, George-st., Edinburgh, price 4*d*.

Appointments.

BROWN, L. G., M.D., B.Ch. Oxf., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Ear, Nose, and Throat Department of Charing Cross Hospital.

GILCHRIST, J., M.D. Edin., one of the Medical Referees under the Workmen's Compensation Act for the county of Lanark.

M'KIE, W., M.B., Ch.B. Edin., Senior Resident Medical Officer at King's Cross Hospital, Dundee.

Certifying Surgeons under the Factory and Workshop Acts: VERITY, R. J. S., L.M.S.S.A. (Abersychan, Monmouth); WALKER, J. B., L.R.C.P. & S. Edin. (Ayr).

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal Mineral Water Hospital.—S.

Birmingham, Rubery Hill and Hollymoor Mental Hospital, Northfield.—Asst. M.O. £350.

Brighton, New Sussex Hospital.—Hon. Asst. Anæsth.

Chesterfield and North Derbyshire Royal Hospital.—R.S.O. £300.

Delhi, Lady Hardinge Medical College.—Lecturer in Physiology. Rs.750 p.m.

East Ham County Borough.—Temp. Asst. M.O.H. £500.

Gloucestershire Royal Infirmary. Gloucester.—P.

Hampstead General Hospital.—Gynæcologist.

Hong-Kong University, Faculty of Medicine.—Professor of Obstetrics and Gynæcology. £800.

Hospital for Consumption, &c., Brompton.—R.M.O. £500.

Hull City Mental Hospital.—Sen. Asst. M.O., &c. £600.

Hull Royal Infirmary.—Asst. House Phys. £130.

Isle of Wight County Mental Hospital.—A.M.O. £300.

King's Lynn, West Norfolk Hospital.—Res. Surg. O. £300–£350.

Kingston Union.—Second A.R.M.O. £300.

Larbert, Stirling District Mental Hospital.—Pathologist. £600.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Liverpool City.—M.O.H. £1800.

London Hospital.—Asst. Phys. Also Second Reg. to Ear, Nose, and Throat Dept.

Lymington, Hants, Borough.—M.O.H. £70.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—H.S. £50.

Margate, Royal Sea Bathing Hospital.—H.S. £200.

Metropolitan Hospital, Kingsland-road, E.—Asst. Dent. S.

Norwich, Norfolk and Norwich Hospital.—Anæsth. £300.

Oldham County Borough—Asst. M.O.H. £450.

Queen's Hospital for Children, Hackney, E.—Asst. Cas. H.S. £100.

Royal Chest Hospital, City-road, E.C.—P. to Out-patients.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and H.S.

Seamen's Hospital Society.—Surgeon.

Sheffield Royal Infirmary.—Med. Reg. £400. Also Ophthalmic H.S. £60.

Sutton, Sutton Downs Hospital for Children.—Jun. Asst. M.O. £500.

University College Hospital, Gower-street, W.C.—Tub. O. £300. Also Non.-Res. House Anæsth. £100.

Ventnor, Royal National Hospital for Consumption, &c.—Sen. Res. M.O. £300.

West London Hospital, Hammersmith-road, W.—Asst. Anæsth.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Hertford, Herts.

Births, Marriages, and Deaths.

BIRTHS.

DAVIES.—On July 4th, at "Plas-Darland," Wrexham, the wife of John E. H. Davies, D.S.O., M.R.C.S., L.R.C.P., of a son.

VAILE.—On July 2nd, at Albert-mansions, Northumberland-street, W., the wife of Dr. T. B. Vaile, of a son.

MARRIAGES.

FARDON—KIRKLAND.—On June 28th, at St. Mark's, Reigate, Harold Joseph Fardon, M.D., to Kathleen Nina, elder daughter of the late Arthur Kirkland, and of Mrs. Kirkland, of South Park, Reigate.

ROSS—TOWNSEND.—On July 5th, at St. Bartholomew-the-Great, London, James Paterson Ross, F.R.C.S., to Marjorie Burton, younger daughter of Captain F. W. Townsend Botley, Hants.

DEATHS.

ELLIOTT.—On July 4th, at Sonning-on-Thames, Edgar Elliott, M.R.C.S., L.R.C.P., late of Sevenoaks, in his 68th year.

NALL.—On June 29th, suddenly, at Furness Vale, Samuel Nall, B.A., M.B., D.P.H., M.R.C.S. Eng. (Camb. and St. Bart.), the beloved husband of Lizzie Nall, aged 69. For many years in practice at Disley.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PART PLAYED BY TRAINING COLONIES IN THE TREATMENT OF TUBERCULOSIS.*

BY F. N. KAY MENZIES, M.D. EDIN., F.R.C.P. EDIN., D.P.H.

THE first reference I can find to the "colony" is a plea by Sir Robert Philip, founded on the experience of the Royal Victoria Hospital, Edinburgh, for the establishment of farm colonies for tuberculous patients. The experience of that sanatorium showed (*a*) that in a number of cases complete arrest of disease could not be attained within the ordinary time-limit of sanatorium residence, and (*b*) that work of a definite character, far from impeding cure, assisted it. The farm colony then, as it was originally called, was a natural evolution of the sanatorium. Its purpose was to serve those tuberculous persons whose disease had been almost completely arrested, but who were found to remain liable to relapse when they returned to their ordinary avocations.

The original conception, therefore, was that with the patient still under medical supervision, his daily life should gradually approximate to the conditions of the ordinary working man's daily existence. The number of hours and the kind of work upon which each patient was engaged were regulated from day to day by the medical superintendent. In addition, some of the colonists, for whom return to their former occupation would mean certain recurrence of their disease, were trained in new pursuits and for them a *definite and suitable post was found before discharge from the colony.* Finally, the continued treatment and training, provided by the original farm colony, was carried out at remarkably low cost. The results were most encouraging and quite a large percentage of the colonists returned to their old occupations and remained well.

Such considerations led to the inclusion of the farm colony in the model tuberculosis scheme adopted by the Departmental Committee on Tuberculosis (1912–13). The problem of the tuberculous ex-Service man and his re-introduction into employment has played the principal part in the development of the colony idea.

We have also to thank the Inter-Departmental Committee (1919), presided over by Sir Montague Barlow, and the work of Dr. P. C. Varrier-Jones, for more recent developments. The report of that Committee stated as to training colonies (*a*) that they were only intended to provide a limited period *of training, usually 6 to 12 months*; (*b*) *that the colonists* were to be subjected to medical control and supervision; and (*c*) that they were only intended to form a stage in the treatment of the patient on the way to ordinary conditions *of life or to more permanent* settlements. The report quite reasonably attached immense importance to the *provision of permanent employment and settlement* under healthy conditions, and, therefore, the Committee made the permanent village settlement their chief recommendation. Shortly afterwards the Ministries of Health and Pensions issued various circulars and memoranda on the subject of vocational training colonies.

Vocational Training Colonies.

Their basic principle is to provide 12 months' training in a suitable occupation so that, at the end of that period, the trainee can leave the colony and support himself by his own exertions. The occupations selected were: pig and poultry farming; market gardening; rural carpentry; clock and watch repairing, &c. There are always a certain number of persons who can and will succeed in making a livelihood of some kind in a new occupation, when a change has to be made in middle life. Even in an ordinary healthy life, however, this is a difficult transition; how much more difficult is it for the tuberculous patient with is impaired life?

To have had any chance of real success the following conditions were essential: (*a*) a more prolonged period of treatment and training; (*b*) a first-rate organisation for securing to the trainees a suitable occupation before leaving; (*c*) an equally first-rate business organisation for marketing their products. Had those essential conditions of success been provided, the outlook to-day might have been very different.

Village Settlements.

The call for the provision of permanent employment and settlement under healthy conditions led the Inter-Departmental Committee to the conclusion that something of the nature of a village settlement on the lines of the Papworth scheme was the most satisfactory solution of the problem of the tuberculous ex-Service men. The arguments in favour were that: (*a*) An ex-Service man is assured of good housing and of industrial occupation while he remains in the settlement; (*b*) he has the advantage and comfort of family life; (*c*) there is general medical supervision in the village settlement; (*d*) there are no advanced cases in this section of the scheme and therefore it would not be regarded as a "Leper Colony." For all practical purposes Papworth Hall and Preston Hall may be taken as best fulfilling the recommendations of the Inter-Departmental Committee, in so far as they are permanent village settlements. In these institutions quite a variety of instruction and occupation is provided in various trades—e.g., carpentry and joinery, cabinet making, portmanteau making, boot making and repairing, horticulture, pig and poultry farming, printing, bee keeping, gamekeeping, hand-made jewellery, &c. These institutions provide beds in their main buildings and in open-air shelters for the treatment of tuberculosis at various stages. There are hostels for single men and cottages for married men and their families. Other features are the payment of reasonable wages to colonists who are employed in the various workshops, and, in addition, the receipt of any disability pension to which they are entitled. Lastly, there is regular medical supervision of the colonists and their families.

---

* Abridged from the opening address at the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis, on July 4th, 1924, in London.

I am not in a position to supply any accurate figures with regard to these two settlements, but it is probably fair to say that the capital expenditure involved in each case is not less than £250,000. Apart, therefore, from the heavy annual cost of maintenance, it is difficult to see how the erection of a number of such settlements by local authorities could be justified as a practical proposition. It must be borne in mind, too, that a large proportion of tuberculous patients are temperamentally unsuitable for colony or settlement life and that a good deal of the success of tuberculosis institutions depends on the personality, inspiration, and power of organisation of those in charge. Permanent village settlements can at the best provide *for a very limited number of T.B. patients*. On these grounds, therefore, the permanent village settlement cannot, for financial and other reasons, be regarded as having proved worthy of inclusion in the national scheme for the treatment of the tuberculous civilian.

Vocational Training Colonies.

Vocational training colonies are, however, in a different category, although in some instances conceived on too ambitious and perhaps somewhat unpractical lines. Again, the mistake has been often made of sending to them men who, by reason of the stage of disease or by temperament and physical condition, could not be regarded as suitable for colony life.

Apart from these fundamental errors, the criticism may be justly made that training rather than treatment appears to be made the paramount consideration, and to make matters worse, the complete absence of any organisation for the provision of a suitable post for every colonist before leaving has been a disastrous oversight.

I plead, therefore, for an immediate realisation and frank recognition of these facts and a return to the sound conceptions upon which the original idea of the colony was based—namely, that the colony is an expansion of the sanatorium for patients for whom extended treatment is necessary. Broadly speaking, the colony at Burrow Hill has realised in considerable degree the aims and objects to which I have referred. Its success, however, would have been enhanced had it been possible to limit admission more rigidly to patients at stages in the disease likely to benefit from the opportunities afforded and it has also suffered from lack of an efficient system of care organisation.

Summary of Fundamental Principles.

In relation to tuberculosis schemes as a whole, we should keep in view certain fundamental principles which may be summarised as follows: (1) Tuberculous infection is almost universal; (2) its obvious manifestations are numerous and vary much in character and degree; (3) attention has hitherto been directed mostly to grosser and later manifestations, notably pulmonary tuberculosis and various forms of crippling; (4) during more recent years it has been demonstrated that tuberculous infection is, in most instances, contracted in childhood, and that later manifestations are, as a rule, resultants of an earlier infection; (5) although infection is thus widespread and generally contracted in childhood, only a small fraction suffer seriously therefrom; (6) the varying character of clinical manifestations is determined largely by varying resistance on the part of the infected individual; (7) in approaching the problem of treatment, attention must be directed to (*a*) the infection [illegible] and (*b*) the degree of resistance which may be offered [illegible]; (8) the aim of treatment should be to reduce [illegible] and to minimise the results of infection: (9) the treatment of an individual patient is successful in proportion as treatment is commenced early. Early treatment may succeed in *de*tuberculising the infected persons *before* the grosser manifestations of the disease have occurred; (10) in proportion as treatment is made effective throughout a community by the applications of physiological—i.e., sanatorium—methods to cases at the *curable* stage, the need for measures, institutional or other, for the grosser manifestations will lessen and in large part disappear. This should be the ultimate aim of tuberculosis schemes. (11) The keynote of the tuberculosis dispensary, tuberculosis school, sanatorium, and training colony is *de*tuberculisation and recovery. (12) The modern conception of the ætiology of tuberculosis emphasises strongly the possibility, and the significance, of early recognition of the infection and deliberate treatment with a view to *de*tuberculisation at the earliest possible moment. (13) That is the outlook and aim of preventive medicine, and must become more and more the outlook and aim of the general *practitioner* as well as the tuberculosis officer.

CARE OF THE FEEBLE-MINDED.

THE annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded was held in the Manchester Town Hall on June 26th. Miss Dendy, its foundress and President, late Commissioner of the Board of Control, occupied the chair in the absence of the Lady Mayoress. The annual report submitted for adoption showed that the 296 places in the Sandlebridge Colony, conducted by the Society, are fully occupied. A new house is in process of building and has been approved by the Board of Control for 25 more patients. The applications for places by public authorities have always been very largely in excess of the number which can be received, thus showing, as has been frequently shown in previous reports, the great lack of residential school provision throughout the country for feeble-minded children. It is the great feature of Sandlebridge that life provision is made for all children received. The report stated that the occupations followed by the women and older girls—housework, laundry work, sewing, and knitting—showed satisfactory progress, and everyone had the pleasure of knowing that her share in the work, if it was only turning the mangle, or picking bits off the mats, or setting the table, had been of use in the daily life of the institution. The girls took great interest in the folk-dancing. In the workshops for the men and older boys boot-making, tailoring, mat-making, brush-making, and weaving was carried on. In submitting the report for adoption, Miss Dendy said that it had become more and more evident that segregation was the only method of dealing with the feeble-minded which was effective as well as proper to be used; there was a growing tendency brought about by the vastness of the problem to think that docile and harmless youths and girls might be dealt with by supervision in their own homes. Docile such patients might be, but nothing could prevent their being potentially dangerous. They were almost sure to become parents either with or without marriage. The speaker continued: "We have under our care two generations of one family, and we have over 200 adults who have been with us since childhood. Had they not been with us how many more to care for would there have been? Eight hundred is a low estimate. Having these children young, they become accustomed to their life and segregation is not the burden to them that it undoubtedly is to many who are cared for only when they have become, at large, an intolerable nuisance. And all of these adults would have been unemployed." The governing body of the Society were re-elected for the coming year and the meeting closed with a vote of thanks to Miss Dendy for her address.

At the annual meeting of the Agatha Stacey Homes, Birmingham, on June 25th, Mrs. Herbert L. Wade, the President, in the chair, the importance of the segregation of the mentally deficient was also emphasised. The report stated that the committee had been compelled during the past year to return some of the older inmates to the care of the Poor-law guardians in order to make room for the younger cases who were in grave moral danger. In seconding the report, Miss Walford, secretary of the Warwickshire Voluntary Association for Mental Welfare, pointed out that the homes were doing invaluable work in protecting the nation from high-grade defectives. These persons, she said, if left at large, cost the taxpayer four times as much as if they were placed in a home. Dr. Marion Burt, school medical officer of Birmingham, said that they hoped greatly to benefit succeeding generations if they could put a satisfactory check on the worst types by means of segregation.

A little over a year ago a small training home for feeble-minded girls at Fairwarp, near Uckfield, was established by the aid of the East Grinstead Case Committee of the East Sussex Voluntary Association for Mental Welfare. The

Appointments.

Brown, L. G., M.D., B.Ch. Oxf., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Ear, Nose, and Throat Department of Charing Cross Hospital.

Gilchrist, J., M.D. Edin., one of the Medical Referees under the Workmen's Compensation Act for the county of Lanark.

M'Kie, W., M.B., Ch.B. Edin., Senior Resident Medical Officer at King's Cross Hospital, Dundee.

Certifying Surgeons under the Factory and Workshop Acts: **Verity, R. J. S.**, L.M.S.S.A. (Abersychan, Monmouth); **Walker, J. B.**, L.R.C.P. & S. Edin. (Ayr).

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal Mineral Water Hospital.—S.
Birmingham, Rubery Hill and Hollymoor Mental Hospital, Northfield.—Asst. M.O. £350.
Brighton, New Sussex Hospital.—Hon. Asst. Anæsth.
Chesterfield and North Derbyshire Royal Hospital.—R.S.O. £300.
Delhi, Lady Hardinge Medical College.—Lecturer in Physiology. Rs.750 p.m.
East Ham County Borough.—Temp. Asst. M.O.H. £500.
Gloucestershire Royal Infirmary, Gloucester.—P.
Hampstead General Hospital.—Gynæcologist.
Hong-Kong University, Faculty of Medicine.—Professor of Obstetrics and Gynæcology. £800.
Hospital for Consumption, &c., Brompton.—R.M.O. £500.
Hull City Mental Hospital.—Sen. Asst. M.O., &c. £600.
Hull Royal Infirmary.—Asst. House Phys. £130.
Isle of Wight County Mental Hospital.—A.M.O. £300.
King's Lynn, West Norfolk Hospital.—Res. Surg. O. £300–£350.
Kingston Union.—Second A.R.M.O. £300.
Larbert, Stirling District Mental Hospital.—Pathologist. £600.
Leeds Public Dispensary.—Sen. Res. M.O. £200.
Liverpool City.—M.O.H. £1800.
London Hospital.—Asst. Phys. Also Second Reg. to Ear, Nose, and Throat Dept.
Lymington, Hants, Borough.—M.O.H. £70.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Manchester Royal Infirmary.—H.S. £50.
Margate, Royal Sea Bathing Hospital.—H.S. £200.
Metropolitan Hospital, Kingsland-road, E.—Asst. Dent. S.
Norwich, Norfolk and Norwich Hospital.—Anæsth. £300.
Oldham County Borough—Asst. M.O.H. £450.
Queen's Hospital for Children, Hackney, E.—Asst. Cas. H.S. £100.
Royal Chest Hospital, City-road, E.C.—P. to Out-patients.
Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and H.S.
Seamen's Hospital Society.—Surgeon.
Sheffield Royal Infirmary.—Med. Reg. £400. Also Ophthalmic H.S. £60.
Sutton, Sutton Downs Hospital for Children.—Jun. Asst. M.O. £500.
University College Hospital, Gower-street, W.C.—Tub. O. £300. Also Non.-Res. House Anæsth. £100.
Ventnor, Royal National Hospital for Consumption, &c.—Sen. Res. M.O. £300.
West London Hospital, Hammersmith-road, W.—Asst. Anæsth.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Hertford, Herts.

Births, Marriages, and Deaths.

BIRTHS.

Davies.—On July 4th, at "Plas-Darland," Wrexham, the wife of John E. H. Davies, D.S.O., M.R.C.S., L.R.C.P., of a son.

Vaile.—On July 2nd, at Albert-mansions, Northumberland-street, W., the wife of Dr. T. B. Vaile, of a son.

MARRIAGES.

Fardon—Kirkland.—On June 28th, at St. Mark's, Reigate, Harold Joseph Fardon, M.D., to Kathleen Nina, elder daughter of the late Arthur Kirkland, and of Mrs. Kirkland, of South Park, Reigate.

Ross—Townsend.—On July 5th, at St. Bartholomew-the-Great, London, James Paterson Ross, F.R.C.S., to Marjorie Burton, younger daughter of Captain F. W. Townsend Botley, Hants.

DEATHS.

Elliott.—On July 4th, at Sonning-on-Thames, Edgar Elliott, M.R.C.S., L.R.C.P., late of Sevenoaks, in his 68th year.

Nall.—On June 29th, suddenly, at Furness Vale, Samuel Nall, B.A., M.B., D.P.H., M.R.C.S. Eng. (Camb. and St. Bart.), the beloved husband of Lizzie Nall, aged 69. For many years in practice at Disley.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PART PLAYED BY TRAINING COLONIES IN THE TREATMENT OF TUBERCULOSIS.*

By F. N. Kay Menzies, M.D. Edin., F.R.C.P. Edin., D.P.H.

The first reference I can find to the "colony" is a plea by Sir Robert Philip, founded on the experience of the Royal Victoria Hospital, Edinburgh, for the establishment of farm colonies for tuberculous patients. The experience of that sanatorium showed (*a*) that in a number of cases complete arrest of disease could not be attained within the ordinary time-limit of sanatorium residence, and (*b*) that work of a definite character, far from impeding cure, assisted it. The farm colony then, as it was originally called, was a natural evolution of the sanatorium. Its purpose was to serve those tuberculous persons whose disease had been almost completely arrested, but who were found to remain liable to relapse when they returned to their ordinary avocations.

The original conception, therefore, was that with the patient still under medical supervision, his daily life should gradually approximate to the conditions of the ordinary working man's daily existence. The number of hours and the kind of work upon which each patient was engaged were regulated from day to day by the medical superintendent. In addition, some of the colonists, for whom return to their former occupation would mean certain recurrence of their disease, were trained in new pursuits and for them a *definite and suitable post was found before discharge from the colony*. Finally, the continued treatment and training, provided by the original farm colony, was carried out at remarkably low cost. The results were most encouraging and quite a large percentage of the colonists returned to their old occupations and remained well.

Such considerations led to the inclusion of the farm colony in the model tuberculosis scheme adopted by the Departmental Committee on Tuberculosis (1912–13). The problem of the tuberculous ex-Service man and his re-introduction into employment has played the principal part in the development of the colony idea.

We have also to thank the Inter-Departmental Committee (1919), presided over by Sir Montague Barlow, and the work of Dr. P. C. Varrier-Jones, for more recent developments. The report of that Committee stated as to training colonies (*a*) that they were only intended to provide a limited period of training, usually 6 to 12 months; (*b*) that the colonists were to be subjected to medical control and supervision; and (*c*) that they were only intended to form a stage in the treatment of the patient on the way to ordinary conditions of life or to more permanent settlements. The report quite reasonably attached immense importance to the *provision of permanent employment and settlement* under healthy conditions, and, therefore, the Committee made the permanent village settlement their chief recommendation. Shortly afterwards the Ministries of Health and Pensions issued various circulars and memoranda on the subject of vocational training colonies.

Vocational Training Colonies.

Their basic principle is to provide 12 months' training in a suitable occupation so that, at the end of that period, the trainee can leave the colony and support himself by his own exertions. The occupations selected were: pig and poultry farming; market gardening; rural carpentry; clock and watch repairing, &c. There are always a certain number of persons who can and will succeed in making a livelihood of some kind in a new occupation, when a change has to be made in middle life. Even in an ordinary healthy life, however, this is a difficult transition; how much more difficult is it for the tuberculous patient with is impaired life?

To have had any chance of real success the following conditions were essential: (*a*) a more prolonged period of treatment and training; (*b*) a first-rate organisation for securing to the trainees a suitable occupation before leaving; (*c*) an equally first-rate business organisation for marketing their products. Had those essential conditions of success been provided, the outlook to-day might have been very different.

Village Settlements.

The call for the provision of permanent employment and settlement under healthy conditions led the Inter-Departmental Committee to the conclusion that something of the nature of a village settlement on the lines of the Papworth scheme was the most satisfactory solution of the problem of the tuberculous ex-Service men. The arguments in favour were that: (*a*) An ex-Service man is assured of good housing and of industrial occupation while he remains in the settlement; (*b*) he has the advantage and comfort of family life; (*c*) there is general medical supervision in the village settlement; (*d*) there are no advanced cases in this section of the scheme and therefore it would not be regarded as a "Leper Colony." For all practical purposes Papworth Hall and Preston Hall may be taken as best fulfilling the recommendations of the Inter-Departmental Committee, in so far as they are permanent village settlements. In these institutions quite a variety of instruction and occupation is provided in various trades—e.g., carpentry and joinery, cabinet making, portmanteau making, boot making and repairing, horticulture, pig and poultry farming, printing, bee keeping, gamekeeping, hand-made jewellery, &c. These institutions provide beds in their main buildings and in open-air shelters for the treatment of tuberculosis at various stages. There are hostels for single men and cottages for married men and their families. Other features are the payment of reasonable wages to colonists who are employed in the various workshops, and, in addition, the receipt of any disability pension to which they are entitled. Lastly, there is regular medical supervision of the colonists and their families.

---

* Abridged from the opening address at the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis, on July 4th, 1924, in London.

I am not in a position to supply any accurate figures with regard to these two settlements, but it is probably fair to say that the capital expenditure involved in each case is not less than £250,000. Apart, therefore, from the heavy annual cost of maintenance, it is difficult to see how the erection of a number of such settlements by local authorities could be justified as a practical proposition. It must be borne in mind, too, that a large proportion of tuberculous patients are temperamentally unsuitable for colony or settlement life and that a good deal of the success of tuberculosis institutions depends on the personality, inspiration, and power of organisation of those in charge. Permanent village settlements can at the best provide *for a very limited number of T.B. patients.* On these grounds, therefore, the permanent village settlement cannot, for financial and other reasons, be regarded as having proved worthy of inclusion in the national scheme for the treatment of the tuberculous civilian.

Vocational Training Colonies.

Vocational training colonies are, however, in a different category, although in some instances conceived on too ambitious and perhaps somewhat unpractical lines. Again, the mistake has been often made of sending to them men who, by reason of the stage of disease or by temperament and physical condition, could not be regarded as suitable for colony life.

Apart from these fundamental errors, the criticism may be justly made that training rather than treatment appears to be made the paramount consideration, and to make matters worse, the complete absence of any organisation for the provision of a suitable post for every colonist before leaving has been a disastrous oversight.

I plead, therefore, for an immediate realisation and frank recognition of these facts and a return to the sound conceptions upon which the original idea of the colony was based—namely, that the colony is an expansion of the sanatorium for patients for whom extended treatment is necessary. Broadly speaking, the colony at Burrow Hill has realised in considerable degree the aims and objects to which I have referred. Its success, however, would have been enhanced had it been possible to limit admission more rigidly to patients at stages in the disease likely to benefit from the opportunities afforded and it has also suffered from lack of an efficient system of care organisation.

Summary of Fundamental Principles.

In relation to tuberculosis schemes as a whole, we should keep in view certain fundamental principles which may be summarised as follows: (1) Tuberculous infection is almost universal; (2) its obvious manifestations are numerous and vary much in character and degree; (3) attention has hitherto been directed mostly to grosser and later manifestations, notably pulmonary tuberculosis and various forms of crippling; (4) during more recent years it has been demonstrated that tuberculosis infection is, in most instances, contracted in childhood, and that later manifestations are, as a rule, resultants of an earlier infection; (5) although infection is thus widespread and generally contracted in childhood, only a small fraction suffer seriously therefrom; (6) the varying character of clinical manifestations is conditioned largely by varying resistance on the part of the infected individual; (7) in approaching the problem of treatment, attention must be directed to (*a*) the infection [illegible] and (*b*) the degree of resistance which may be offered to its attack; (8) the aim of treatment should be to reduce, as far as [illegible] [illegible] of exposure to [illegible], and to minimise the results of infection; (9) the treatment of an individual patient is successful in proportion as treatment is commenced early. Early treatment may succeed in *de*tuberculising the infected persons *before* the grosser manifestations of the disease have occurred: (10) in proportion as treatment is made effective throughout a community by the applications of physiological—i.e., sanatorium—methods to cases at the *curable* stage, the need for measures, institutional or other, for the grosser manifestations will lessen and in large part disappear. This should be the ultimate aim of tuberculosis schemes. (11) The keynote of the tuberculosis dispensary, tuberculosis school, sanatorium, and training colony is *de*tuberculisation and recovery. (12) The modern conception of the ætiology of tuberculosis emphasises strongly the possibility, and the significance, of early recognition of the infection and deliberate treatment with a view to *de*tuberculisation at the earliest possible moment. (13) That is the outlook and aim of preventive medicine, and must become more and more the outlook and aim of the general practitioner as well as the tuberculosis officer.

CARE OF THE FEEBLE-MINDED.

THE annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded was held in the Manchester Town Hall on June 26th. Miss Dendy, its foundress and President, late Commissioner of the Board of Control, occupied the chair in the absence of the Lady Mayoress. The annual report submitted for adoption showed that the 296 places in the Sandlebridge Colony, conducted by the Society, are fully occupied. A new house is in process of building and has been approved by the Board of Control for 25 more patients. The applications for places by public authorities have always been very largely in excess of the number which can be received, thus showing, as has been frequently shown in previous reports, the great lack of residential school provision throughout the country for feeble-minded children. It is the great feature of Sandlebridge that life provision is made for all children received. The report stated that the occupations followed by the women and older girls—housework, laundry work, sewing, and knitting—showed satisfactory progress, and everyone had the pleasure of knowing that her share in the work, if it was only turning the mangle, or picking bits off the mats, or setting the table, had been of use in the daily life of the institution. The girls took great interest in the folk-dancing. In the workshops for the men and older boys boot-making, tailoring, mat-making, brush-making, and weaving was carried on. In submitting the report for adoption, Miss Dendy said that it had become more and more evident that segregation was the only method of dealing with the feeble-minded which was effective as well as proper to be used; there was a growing tendency brought about by the vastness of the problem to think that docile and harmless youths and girls might be dealt with by supervision in their own homes. Docile such patients might be, but nothing could prevent their being potentially dangerous. They were almost sure to become parents either with or without marriage. The speaker continued: "We have under our care two generations of one family, and we have over 200 adults who have been with us since childhood. Had they not been with us how many more to care for would there have been? Eight hundred is a low estimate. Having these children young, they become accustomed to their life and segregation is not the burden to them that it undoubtedly is to many who are cared for only when they have become, at large, an intolerable nuisance. And all of these adults would have been unemployed." The governing body of the Society were re-elected for the coming year and the meeting closed with a vote of thanks to Miss Dendy for her address.

At the annual meeting of the Agatha Stacey Homes, Birmingham, on June 25th, Mrs. Herbert L. Wade, the President, in the chair, the importance of the segregation of the mentally deficient was also emphasised. The report stated that the committee had been compelled during the past year to return some of the older inmates to the care of the Poor-law guardians in order to make room for the younger cases who were in grave moral danger. In seconding the report, Miss Walford, secretary of the Warwickshire Voluntary Association for Mental Welfare, pointed out that the homes were doing invaluable work in protecting the nation from high-grade defectives. These persons, she said, if left at large, cost the taxpayer four times as much as if they were placed in a home. Dr. Marion Burt, school medical officer of Birmingham, said that they hoped greatly to benefit succeeding generations if they could put a satisfactory check on the worst types by means of segregation.

A little over a year ago a small training home for feeble-minded girls at Fairwarp, near Uckfield, was established by the aid of the East Grinstead Case Committee of the East Sussex Voluntary Association for Mental Welfare. The first annual report of the home has just been issued and shows that the 15 beds with which it was provided are now full. The cost of the home for the year has been £750, which has been met by the payment of £1 per week for each inmate. Only three of the girls admitted have so far proved unsuitable for residence, and the progress made by all the girls in the year seems to the committee to be most satisfactory. An effort has been made to train the girls among pleasant surroundings, to render themselves at least partially self-supporting. The committee hopes to be in a position shortly to increase the scope of the work, and by raising a case fund to provide a free, or nearly free, bed for a local case.

PORTABLE RADIOGRAPHS.

The lack of efficient radiographic facilities is often a severe handicap to the practitioner whose work lies at some distance from the nearest hospital or private installation. To these practitioners the services of a firm possessing complete portable equipment for all kinds of radiographic work should be of great value. A firm known as "Portable Radiographs," of 1, Woodstock-road, Bedford Park, London, W. 4, now undertakes work of this description. The apparatus employed has been specially designed, and is transported in a plain, closed motor, the engine of which supplies the necessary electric current. From the special alternator mounted on the bonnet of the car two wires are led through a convenient window in the sick-room, and are connected at the bedside to the portable X ray apparatus, which is not bulky. At a recent demonstration the complete apparatus was installed and connected in the space of half an hour, three radiograms were taken and developed in the motor-car, and were ready in the course of a few minutes. The whole procedure was efficiently carried out and the definition of the radiograms was excellent. Screen-work can also be undertaken and a screening couch is carried. The firm informs us that it undertakes work for the medical and dental professions only, and that further the staff works under the instruction of the medical man in charge of the case. The various applications of such service are sufficiently obvious. We understand that the apparatus was employed in connexion with the recent Rodeo exhibition at Wembley.

CURATIVE RHYTHM AND THE PRACTITIONER.

To the Editor of The Lancet.

Sir,—Will you permit me to draw the attention of medical men to the treatment known as "curative rhythm" instituted by Miss Anne Walton? Some years ago I wrote a pamphlet entitled "Created Rhythm," in which I pointed out that this treatment is based on the same rhythmic power that seeks expression through nature, music, our varied sciences, arts, literature, &c. I then pleaded that this new treatment should be tested by the medical profession to prove its justification in the same way that massage and suggestion therapy have been tested. I am glad to say that it is becoming more recognised by large numbers of the medical profession that rhythm acts not only as a powerful eliminator of mental and physical disabilities, but also as a powerful mental and physical recuperative. The treatment has been developed quietly in coöperation with medical men, but there are still large numbers who have never heard of it. The method includes relaxation, rhythmic manipulation, suggestion therapy, rhythmic movements combined with breathing. Some of the disorders which have been successfully treated by this method are insomnia, neurasthenia, neuritis, habit spasms, writers' cramp, lack of concentration, faulty posture, and dyspepsia.

Further information can be obtained from the secretary, 24, Welbeck-street, Cavendish-square, W. 1, where this treatment is being carried on. It is also available at Brighton and Harrogate.

I am, Sir, yours faithfully,

Theo. B. Hyslop, M.D., F.R.S.E.

Portland-place, W., *June 26th, 1924.*

PUBLIC HEALTH IN BIHAR AND ORISSA.

With an abundant rainfall, generally favourable in its distribution, the year 1922 was the most prosperous and healthy which this province had known for a considerable period, and was specially characterised by the absence of any important epidemic disease. The death-rate was 24·1 per 1000, as compared with 32·8 in 1921, 39·6 for the preceding five years, and 35·3 for the decennium. The population (census of 1921) was 34,002,189 (not including the tributary States of Orissa, the vital occurrences in which are not included in this report). The birth-rate was 35·0 per 1000, compared with 34·6 in 1921, and 38·4 in the preceding decennium. In Purnea district it was only 26·3; in Angul it was 42·9. The ratio for rural areas was 35·2; for towns 30·0 per 1000. Among the former it varied from 26·5 in Purnea to 42·9 in Angul; for the latter, from 11·1 at Dhanbad and 12·7 at Giridih, to 48·9 at Lalganj and 49·2 at Hajipur. "The low birth-rate recorded in Dhanbad and Giridih is probably due to the large floating population connected with the coal-mines, and to the excess of males in the population of such towns. Defective reporting is also probable, owing to the population of these towns being migratory." Lieut.-Colonel W. C. Ross, Director of Public Health for the province, who presents this report,[1] considers with regard to the death-rate, "that it is unlikely that this high standard will be maintained in future years, but the low rate now reported shows clearly what is possible when conditions are favourable, and what may again be achieved if steady progress is made in the improvement of sanitary conditions." It may be hoped (and indeed expected) that this high standard *will* be maintained. The results of progress are evident, and themselves constitute an encouragement for continuance in the right direction. In regard to infantile mortality the ratio per 1000 births was 139·9, as compared with 159·0 in 1921; in the towns it was 165·9, and in the rural areas 139·1. As to class, or religious persuasion, amongst Hindus, who form the bulk of the population, the death-rate was 24·7; for Mohammedans 20·7; for Christians 14·4; and for "other classes" 22·8 per 1000. In regard to vital statistics Colonel Ross emphasises their importance and utility, regarding them as "the barometer of public health. . . . Let us accept the proposition that public health is an economic question and must be dealt with accordingly."

The general death-rate of the province, as already mentioned, was only 24·1 per 1000; of this total, 17·0 per 1000 is ascribed to "fevers," as compared with 22·6 in 1921, and 27·4, the quinquennial average. This improvement (as regards the average) was manifest in every district of every division. The highest fever mortality ratios were returned from the districts of Palamau (22·1), Muzaffarpur (20·6), and Shahabad (20·3), where the quinquennial averages had been 33·6, 29·1, and 36·2 per 1000 respectively. In Angul district, where the quinquennial fever mortality had been higher than in any other (37·6), the ratio fell to 19·6. Cholera caused 26,805 deaths (0·7 per 1000), all of which, except 852, occurred in the rural areas; and the same ratio per 1000 (0·7) applies equally to these areas and to the towns. The improvement was very great as compared with 2·6 in the previous year, and 3·1 in the quinquennium. In the various districts the mortality ranged from 0·005 in Angul and Singhbhum, and 0·006 in Ranchi, to 2·3 in Muzaffarpur and 4·7 in Balasore. It is satisfactory to learn that "the use of permanganate of potash and chlorinated lime for disinfecting wells has now been generally adopted by local bodies, and the procedure is now generally known and appreciated."

ARTIFICIAL LIMBS.

We have received from Messrs. W. R. Grossmith, Ltd., a small pamphlet entitled "Nature Reproduced," in which are recorded some of the achievements of amputees who use the artificial limbs of this well-known firm. The merits of the "Anglesey" pattern artificial leg, which has been in use in this country since the middle of the last century, have long been known, but have been perhaps unduly overshadowed by the successes achieved by American types, especially those modified and improved by British makers during the war. Nevertheless, the fact remains that Anglesey legs, when properly made and fitted, can be as light as, or even lighter than, any other limbs upon the market, whether made of metal, leather, wood, or composition; their wearers have achieved notable successes in walking competitions and have taken part in all manner of sports and occupations. Their durability when fairly used is shown by the testimony of amputees who have worn the same limb for 20 or 30 years. Recognition of the merits of one type of limb by no means implies condemnation of other types, for in prosthetics the proverb "One man's meat is another man's poison" is most emphatically true. *The personal equation is one of the most important factors in the solution of the problems of prosthetics, and here, again, the man is more than the machine.*

An Address
ON
CHRONIC DIARRHŒA.

Delivered before the Derby Medical Society on March 13th, 1924,

By JOHN A. RYLE, M.D., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

For those of us who are chiefly concerned with clinical problems it is often profitable to discuss the natural history of a single symptom; to consider its several origins and types; and generally to pass in review the diagnostic difficulties to which it may give rise. Such a survey should include a valuation of the methods available for the investigation of the symptom, and should have as one of its aims the practical consideration of how to rationalise treatment. I have chosen as my topic chronic diarrhœa, under which heading may be included recurring or intermittent types of the complaint. I shall, wherever possible, base my remarks on personal clinical observations, referring only to such special or experimental work as seems to have a direct and useful bearing on the question. By diarrhœa we should imply—to quote a formula of J. Ch. Roux—"the too rapid evacuation of too fluid stools," in this way avoiding confusion with certain pseudo-diarrhœas. So far as its actual incidence in practice is concerned, I imagine chronic diarrhœa would not, in our climate and at ordinary times, be regarded as a very common symptom. Nevertheless it is a symptom common to a great variety of diseases, and it may be a very troublesome one to analyse and treat. Furthermore, by reason of the wide extent of our Empire, increasing facilities for travel, and the recent ravages of war, certain types of infective diarrhœa have undoubtedly become more common in this country than they were in previous decades.

For the patient the symptom is mainly a subjective one—that is to say, it is the sensory discomforts and inconveniences which urge him to seek advice. It has, however, an advantage over more strictly subjective experiences in that it is accompanied by the passage of abnormal stools, with regard to the nature and number of which more or less accurate observations are possible. In no type of chronic diarrhœa can we afford to neglect such observations. Sometimes they declare or suggest the diagnosis at once. In all cases they give guidance as to the necessary collateral inquiries. There can be no doubt that modern perfections in domestic sanitation, however great their benefits, have served to hinder the modern physician, and to render him less familiar with the appearances of normal and abnormal fæcal discharges than were his predecessors. It will be within the experience of many of us, too, that the sensibilities of the patient occasionally offer a strong resistance to our attempts to inspect a stool. For these and other reasons the routine inspection and special examination of fæcal specimens have never received the thorough attention accorded to the urinary excretions. I shall have occasion to refer in more detail to this matter as my theme develops.

Classification.

Before we can discuss the several types of diarrhœa and their differential features some form of classification is desirable. The best clinical classifications are usually those based on causal pathology. It so happens in the case of chronic diarrhœa that an anatomical classification of the sites of origin of the symptom is more convenient, and at the same time permits of a clear review of the underlying morbid processes. Thus, by considering in succession the stomach, the small bowel, the large bowel and rectum, and the accessory glands and structures communicating with the di[illegible] (in particular the pancreas, the gall-bladder, and the absorptive apparatus comprising the lacteals and mesenteric glands) we cover the origins of all the important varieties of chronic diarrhœa, with the exception of those depending on external nervous stimuli or due to such complex factors as obtain in the case of Graves's disease.

Those due to nervous factors include a rare form of tabetic diarrhœa, diarrhœa due to reflex stimulation from a neighbouring visceral lesion, and emotional diarrhœa. To diarrhœa of gastric origin the term gastrogenous has been applied, and we might for brevity speak similarly of enterogenous, cologenous, pancreatogenous, psychogenous diarrhœa, and so forth. Such adjectives, however, are open to criticism and do not adequately indicate the cause of the symptom. Diarrhœas may also be broadly classified into those dependent upon functional digestive errors and those dependent upon organic and usually ulcerative intestinal disease. With most of us it will probably have been a natural inclination to regard diarrhœa as essentially a bowel symptom. It is, however, no more essentially a symptom of primary bowel disease than tachycardia is a symptom of heart disease, or dyspepsia of stomach disease. At the outset, therefore, the classification which I have suggested reminds us of the necessity in an individual case of reviewing widely diverse possibilities, and of arranging our interrogation of the patient in such a way as to obtain information relating to the function of many parts.

Methods of Investigation.

Assuming a careful history to have been taken and a routine overhaul made, it becomes necessary to consider what special examinations should be conducted in a given case. These examinations may be usefully subdivided into (*a*) essential clinical examinations; (*b*) valuable and often essential accessory investigations which yet fall within the scope and province of the clinician; (*c*) special examinations for which it is usually preferable to obtain the coöperation of an expert in chemical, bacteriological, or radiographic methods.

The essential clinical examinations include inspection of the stools and a rectal examination, and should, strictly speaking, be omitted in no case of chronic diarrhœa.

The accessory investigations falling within the province of the clinician, but in which he may sometimes elect to obtain coöperation, include a direct inspection of the rectum or sigmoid through a proctoscope or sigmoidoscope; a simple microscopic examination of the stools for blood, pus, meat-fibres, &c.; a chemical examination of the stools for the presence of blood, or of a filtrate of the stools for albumin; and occasionally the examination of a blood film. Observing the rate of passage of charcoal given by the mouth is another simple and sometimes useful test.

The special laboratory examinations include gastric analysis; examination of the stools for amœbæ, cysts, parasites and ova, fatty crystals, &c.; chemical analyses of the fatty content of the stools; tests for pancreatic efficiency, and various bacteriological and serological procedures. For the study of the stools with a view to estimating the utilisation of various foodstuffs it may be necessary to employ a special diet, such as that recommended by Schmidt. The radiologist may give useful information as to the rate of passage of an opaque meal through various portions of the alimentary tract, and after an opaque enema may sometimes provide positive evidence of the presence of a colonic growth.

Diarrhœa of Gastric Origin.

The text-books of general medicine accord little or no space to the consideration of this interesting group of diarrhœas, nor does it appear to be widely recognised in practice. Nevertheless it is one of the most important. Numerically it accounts for more cases than any other single group excepting the colonic group. In the majority of cases of gastric diarrhœa there is a great diminution or complete absence of

the free hydrochloric acid of the gastric juice, and to the extent that *complete* relief of the diarrhœa is nearly always afforded by the therapeutic administration of dilute hydrochloric acid it would seem that the deficiency is in itself an essential factor.

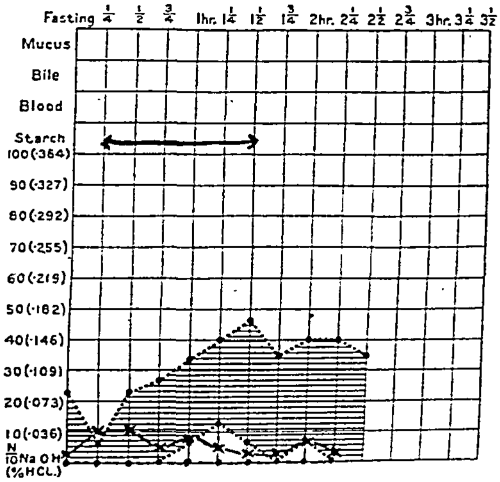
Achlorhydria may be primary or secondary. It may depend either on a true and possibly inherited absence of the normal secretion, in which case the title achylia gastrica becomes applicable, or upon factors causing excessive neutralisation, such as oversecretion of mucus and an undue degree of duodenal regurgitation. Achlorhydria may be unaccompanied by any symptoms whatsoever, and was found by Bennett and myself[1] in 4 per cent. of 100 healthy students. It occurs in upwards of 10 per cent. of dyspeptics and in a great variety of other conditions. It is common but not constant in pellagra and sprue, in chronic gastritis, and in malignant disease. In Addison's anæmia and subacute combined degeneration of the cord it occurs in almost every case. Diarrhœa may be the only symptom of achlorhydria. In Addison's anæmia it is important to recognise that it may antedate the appearance of the anæmia and other classical signs by months or even by many years.

The clinical features of a case of simple gastric diarrhœa are as follows. The evacuations are not as a rule very frequent, three or four stools in the course of the day being a common account, though occasionally they may be as numerous as six or eight. They are generally entirely unaccompanied by pain or colicky sensations—an important point in differentiating them from intestinal diarrhœas. The stools are loose and unformed rather than fluid. Owing to their rapid passage through the alimentary tract they are of a paler brown than the average normal stool. They contain neither mucus nor blood. In virtue of their rapid passage they may show microscopically the presence of undigested meat fibres. Schmidt[2] pointed out that on a diet including raw or underdone meat connective tissue particles (which can only undergo digestion in the presence of gastric juice) may be readily recognised in the fæces of patients with gastric hurry and hyposecretion. The diarrhœa has a *tendency to occur in the early morning* and to be precipitated by meals. Associated symptoms, if any, are referred rather to the stomach than elsewhere. Epigastric discomfort, slight nausea and sinking feelings, intolerance of alcohol, fats, soups, and fluid meals are among the subjective complaints. In a secondary achlorhydria due to gastritis of alcoholic origin, or due to gross oral sepsis, morning nausea and retching may be present. Acne rosacea was shown by Barber and myself[3] to be associated with achlorhydria in a high proportion of cases, and I have more than once been persuaded of the gastric origin of a chronic diarrhœa by the coexistence of this unmistakable skin lesion. Abdominal and rectal examinations are negative. Careful steps should always be taken to exclude Addison's anæmia, and splenic enlargement or a history of sore tongue or of sensory manifestations pointing to central nervous disease should be seriously regarded.

A fractional test-meal in the majority of cases shows complete absence of free acid throughout the meal, and a very low curve of total acidity. Usually there is rapid emptying, the stomach sometimes being void within a half to three-quarters of an hour instead of in the more usual period of two hours. A radiographic examination with an opaque meal shows a similar rapid emptying and rapid passage throughout the intestinal tract. This rapid evacuation of the stomach, with consequent over-stimulation of activity in the small intestine (and possibly inadequate stimulation of the pancreas) is the actual cause of the diarrhœa. The remarkable and almost constant response to the therapeutic administration of dilute hydrochloric acid in these cases suggests that the acid-control of the pylorus may play a more important part in the behaviour of this sphincter than physiologists have latterly been inclined to allow. The therapeutic test of giving acid may be an important diagnostic point when other methods of investigation are not available.

The treatment includes, where possible, the removal of any likely cause of a secondary achlorhydria, such as alcoholic excess or dental sepsis. An alcoholic diarrhœa, perhaps more commonly seen in beer-drinkers than spirit-drinkers, will improve or clear up altogether if the patient succeeds in altering his habits, and it can be shown that an achlorhydria may under these circumstances be replaced by a normal secretory curve. In simple, unexplained diarrhœa associated with achlorhydria, in Addison's anæmia, and in subacute combined degeneration of the cord, hydrochloric acid should always be given. As the antiseptic, as well as the physiological action of acid, is probably of real importance it should, in fact, be prescribed over long periods or continuously in every case of achlorhydric diarrhœa. Doses as small as 10 or 20 minims of the dilute preparation three times a day may be successful in checking the frequent evacuations, but if antisepsis is aimed at doses of a drachm or more should be given. Taken with lemonade or orangeade with the three main meals it is quite a pleasant beverage. I have also seen one or two cases of chronic diarrhœa, apparently of gastric origin, in which complete relief followed the taking of acid, notwithstanding that gastric analysis gave normal figures.

The following case is instructive. In the early stages the patient's symptoms were those of a simple gastric diarrhœa, but were not recognised as such. Later he developed Addison's anæmia. The accompanying chart illustrates the test-meal findings characteristic of both conditions.



The shaded area represents the limits for free HCl. of 80% of normal people.

●——● represents free HCl.

×——× represents total acidity.

A middle-aged man came under observation on account of severe anæmia, with a history of breathlessness and failing strength of about one year's duration. For nine years he had been troubled by a chronic painless type of diarrhœa. Seven years previously an X ray examination had shown a rapidly emptying stomach and exceedingly rapid evacuation of the barium. The blood picture was typical of Addison's anæmia, and a test-meal showed complete achlorhydria. Within 24 hours of starting to take hydrochloric acid the diarrhœa was entirely controlled.

Diarrhœa After Gastro-enterostomy.

One other type of gastric diarrhœa resulting from unsuccessful or *too* successful surgery deserves mention. From time to time one sees patients who have had a gastro-enterostomy performed, and have thereafter developed chronic or intermittent diarrhœa. There are two types, a benign one which is fortunately the more common, and a rare one associated with other and graver symptoms. The benign type closely simulates the simple gastric diarrhœa already described. It is due to a too patent stoma causing excessively rapid emptying, with the result that there is no time for gastric digestion to take place. There is over-neutralisation of the gastric juice, and consequently an artificial achlorhydria; pancreatic secretion, and certainly exposure to pancreatic secretion, may also be inadequate. The stools are light in colour, and may show fatty crystals and meat fibres, but no blood. There is no pain, but there is often discomfort referred to the small bowel area surrounding the navel and occurring almost immediately after food. In a case of this kind recently under my care the patient had once noticed fragments of egg white in the stools within half an hour of their ingestion; X rays showed the stomach to be empty in ten minutes; test-meal showed achlorhydria, and the stools contained soaps, fatty acids, and meat fibre in excess of normal. Dry meals, lying down after the main meals, and the administration of acid (provided there is no persisting evidence of gastric, duodenal, or jejunal ulceration) often give relief, and pancreatin may be helpful.

The serious type is due to the development of a jejuno-colic fistula as the result of jejunal ulceration. In such cases pain, great emaciation, and vomiting may be present in addition to the diarrhœa, and gastric acidity is likely to be high.

DIARRHŒA ORIGINATING IN THE SMALL BOWEL.

There is only one important cause of diarrhœa in this group—namely, tuberculous ulceration of the ileum. For this reason diagnosis should seldom be in doubt as (excepting in the far less common variety of localised ileo-cæcal tuberculosis) there is nearly always active coexisting lung disease or abdominal tuberculosis. The frequency of the calls to stool is very variable, and it should, of course, be recognised that ulceration may be present with constipation. Generally the frequency bears some kind of relation to the extent of the disease. A common story is four to six actions daily—a rather higher average figure than in most cases of gastric diarrhœa, but a lower one than obtains in ulcerative lesions of comparable severity in the large bowel. In contradistinction to the gastric group pain is a frequent and troublesome association. It is usually referred to the peri-umbilical and right iliac zones, and tenderness in the right iliac fossa is commonly present. There is the same post-prandial tendency to looseness as in the diarrhœas of gastric origin, and hot soups and fluids are especially disturbing. The stools are soft or semi-fluid, and light in colour. It is rare for macroscopic blood or mucus to be present, but positive results with the benzidine, guaiac, and spectroscopic tests are obtainable. If the ulceration be very extensive, and particularly if there be much involvement of the mesenteric glands causing obstruction to the lymphatic flow, the stools may be copious and chalky-looking and contain excess of fats and soaps, while in virtue of the diarrhœa undigested meat fibres may be present. With appropriate technique tubercle bacilli can also be demonstrated.

Treatment in these cases can only be palliative, but Gull[4] pointed out as long ago as 1855 the importance of avoiding the then common practice of giving cod-liver oil or a diet rich in milk and cream in cases of tuberculous disease in which fat absorption is at fault.

DIARRHŒA ORIGINATING IN DISEASE OF THE COLON AND RECTUM.

This is a most important group, and is more beset with difficulties than either of those to which I have referred. It includes the chronic phases of amœbic and bacillary dysentery, other forms of infective ulceration of the colon of unspecified origin, non-ulcerative types or stages of colitis, malignant ulceration of the colon and rectum, the terminal colitis of Bright's disease, certain spurious forms of colitis and diarrhœa, such as that which is commonly classified as "muco-membranous," and those due to constipation, abuse of purgatives, and excess of douching. In this group more than any other careful rectal examination, direct inspection of the mucosa through a sigmoidoscope, and macroscopic and microscopic examinations of the stools are of importance. It is in this group that serious mistakes are made through omission of simple examinations. It will probably have been within the experience of many of us to discover a rectal carcinoma, perhaps in a patient below the common age, primarily regarded and treated, sometimes for months, as a case of "diarrhœa," "colitis," or "piles." I see two or three such cases every year, and there are other pitfalls; I have, for instance, in the last two years seen three patients who had at some previous date suffered from dysentery or ulcerative colitis, but in whom a carcinoma of the colon had subsequently developed and been missed in spite of careful investigations. The old story of colitis or dysentery had served to lull suspicion instead of rousing it, for there is, I believe, a definitely increased liability to malignancy in persons who have previously suffered from chronic infective ulceration of the large bowel.

In a considerable proportion of all cases of diarrhœa from active colonic or rectal ulceration, from whatever cause, blood, mucus, and sometimes pus will have been observed by the patient himself at some period of his illness. So long as ulceration persists blood will be demonstrable microscopically and chemically, if not macroscopically, for the cells have not, as in bleeding at a higher level, had time to undergo disintegration. Leucocytes much more readily undergo disintegration, and for this reason their presence in large numbers points to a lesion low down in the large bowel or to an abscess discharging thereinto. Goiffon[5] states that albumin in the filtrate from a fæcal emulsion is a reliable index of the presence of active bowel ulceration, but I have not employed the test myself. Pain, both colicky and (if there is extensive inflammation of the wall of the bowel) more continuous, and accompanied by tenderness, is a frequent but not constant association of all ulcerative forms of colitis. It is commonly referred to the lower abdomen, and especially to the region of the descending colon and rectum, and is most in evidence during or after defæcation. The diarrhœa may be continuous or intermittent and, particularly in cases of malignant disease, may alternate with constipation. In an acute phase the evacuations are frequent and small, and consist largely of blood, mucus, and sometimes pus. In the more chronic phases they may be watery and intermixed with fæcal material, the blood and mucus being less conspicuous. With growths low down in the colon and in the rectum the blood may sometimes be so intimately mixed with a watery brown malodorous evacuation as to escape the patient's notice. When not sufficiently obvious on a casual inspection blood and mucus can often be made apparent by gently tilting the bed-pan—a receptacle which should always be employed in preference to others in suspicious cases; the viscid mucous fragments are then seen to slide more slowly across the white field than the fluid elements of the stool. Washing with water may also bring abnormal particles to light.

The Dysenteries.

In the case of the dysenteries it is important to recognise that both varieties (though more rarely that due to *Entamœba histolytica*) may be acquired in this country, and that relapses after periods of good health are common. Of the two the amœbic variety is the more likely to give rise to a chronic mild diarrhœa with little or no pain. The asylum dysenteries have been shown to be generally due to bacillary infections, and Hurst[6] has suggested that a considerable proportion of the sporadic cases formerly classified as "ulcerative colitis" are in reality chronic bacillary dysentery. From the point of view of the morbid changes in the mucosa no distinction can be drawn between chronic bacillary dysentery and chronic "ulcerative colitis," and a certain proportion of cases of the latter show a very remarkable response to treatment with polyvalent anti-dysentery serum. When it is remembered that only a comparatively the free hydrochloric acid of the gastric juice, and to the extent that complete relief of the diarrhœa is nearly always afforded by the therapeutic administration of dilute hydrochloric acid it would seem that the deficiency is in itself an essential factor.

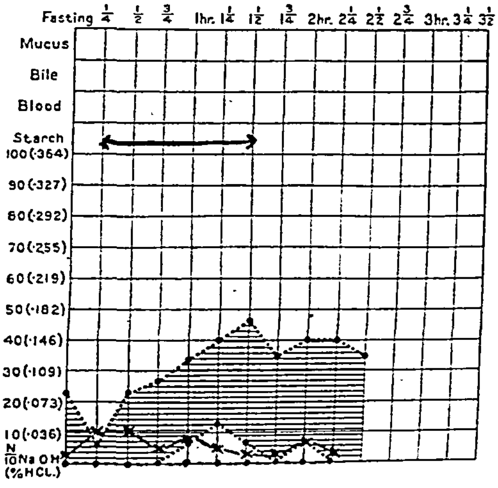
Achlorhydria may be primary or secondary. It may depend either on a true and possibly inherited absence of the normal secretion, in which case the title achylia gastrica becomes applicable, or upon factors causing excessive neutralisation, such as over-secretion of mucus and an undue degree of duodenal regurgitation. Achlorhydria may be unaccompanied by any symptoms whatsoever, and was found by Bennett and myself[1] in 4 per cent. of 100 healthy students. It occurs in upwards of 10 per cent. of dyspeptics and in a great variety of other conditions. It is common but not constant in pellagra and sprue, in chronic gastritis, and in malignant disease. In Addison's anæmia and subacute combined degeneration of the cord it occurs in almost every case. Diarrhœa may be the only symptom of achlorhydria. In Addison's anæmia it is important to recognise that it may antedate the appearance of the anæmia and other classical signs by months or even by many years.

The clinical features of a case of simple gastric diarrhœa are as follows. The evacuations are not as a rule very frequent, three or four stools in the course of the day being a common account, though occasionally they may be as numerous as six or eight. They are generally entirely unaccompanied by pain or colicky sensations—an important point in differentiating them from intestinal diarrhœas. The stools are loose and unformed rather than fluid. Owing to their rapid passage through the alimentary tract they are of a paler brown than the average normal stool. They contain neither mucus nor blood. In virtue of their rapid passage they may show microscopically the presence of undigested meat fibres. Schmidt[2] pointed out that on a diet including raw or underdone meat connective tissue particles (which can only undergo digestion in the presence of gastric juice) may be readily recognised in the fæces of patients with gastric hurry and hyposecretion. The diarrhœa has a tendency to occur in the early morning and to be precipitated by meals. Associated symptoms, if any, are referred rather to the stomach than elsewhere. Epigastric discomfort, slight nausea and sinking feelings, intolerance of alcohol, fats, soups, and fluid meals are among the subjective complaints. In a secondary achlorhydria due to gastritis of alcoholic origin, or due to gross oral sepsis, morning nausea and retching may be present. Acne rosacea was shown by Barber and myself[3] to be associated with achlorhydria in a high proportion of cases, and I have more than once been persuaded of the gastric origin of a chronic diarrhœa by the coexistence of this unmistakable skin lesion. Abdominal and rectal examinations are negative. Careful steps should always be taken to exclude Addison's anæmia, and splenic enlargement or a history of sore tongue or of sensory manifestations pointing to central nervous disease should be seriously regarded.

A fractional test-meal in the majority of cases shows complete absence of free acid throughout the meal, and a very low curve of total acidity. Usually there is rapid emptying, the stomach sometimes being void within a half to three-quarters of an hour instead of in the more usual period of two hours. A radiographic examination with an opaque meal shows a similar rapid emptying and rapid passage throughout the intestinal tract. This rapid evacuation of the stomach, with consequent over-stimulation of activity in the small intestine (and possibly inadequate stimulation of the pancreas) is the actual cause of the diarrhœa. The remarkable and almost constant response to the therapeutic administration of dilute hydrochloric acid in these cases suggests that the acid-control of the pylorus may play a more important part in the behaviour of this sphincter than physiologists have latterly been inclined to allow. The therapeutic test of giving acid may be an important diagnostic point when other methods of investigation are not available.

The treatment includes, where possible, the removal of any likely cause of a secondary achlorhydria, such as alcoholic excess or dental sepsis. An alcoholic diarrhœa, perhaps more commonly seen in beer-drinkers than spirit-drinkers, will improve or clear up altogether if the patient succeeds in altering his habits, and it can be shown that an achlorhydria may under these circumstances be replaced by a normal secretory curve. In simple, unexplained diarrhœa associated with achlorhydria, in Addison's anæmia, and in subacute combined degeneration of the cord, hydrochloric acid should always be given. As the antiseptic, as well as the physiological action of acid, is probably of real importance it should, in fact, be prescribed over long periods or continuously in every case of achlorhydric diarrhœa. Doses as small as 10 or 20 minims of the dilute preparation three times a day may be successful in checking the frequent evacuations, but if antisepsis is aimed at doses of a drachm or more should be given. Taken with lemonade or orangeade with the three main meals it is quite a pleasant beverage. I have also seen one or two cases of chronic diarrhœa, apparently of gastric origin, in which complete relief followed the taking of acid, notwithstanding that gastric analysis gave normal figures.

The following case is instructive. In the early stages the patient's symptoms were those of a simple gastric diarrhœa, but were not recognised as such. Later he developed Addison's anæmia. The accompanying chart illustrates the test-meal findings characteristic of both conditions.



The shaded area represents the limits for free HCl. of 80% of normal people.

A middle-aged man came under observation on account of severe anæmia, with a history of breathlessness and failing strength of about one year's duration. For nine years he had been troubled by a chronic painless type of diarrhœa. Seven years previously an X ray examination had shown a rapidly emptying stomach and exceedingly rapid evacuation of the barium. The blood picture was typical of Addison's anæmia, and a test-meal showed complete achlorhydria. Within 24 hours of starting to take hydrochloric acid the diarrhœa was entirely controlled.

Diarrhœa After Gastro-enterostomy.

One other type of gastric diarrhœa resulting from unsuccessful or too successful surgery deserves mention. From time to time one sees patients who have had a gastro-enterostomy performed, and have thereafter developed chronic or intermittent diarrhœa. There are two types, a benign one which is fortunately the more common, and a rare one associated with other and graver symptoms. The benign type closely simulates the simple gastric diarrhœa already described. It is due to a too patent stoma causing excessively rapid emptying, with the result that there is no time for gastric digestion to take place. There is over-neutralisation of the gastric juice, and consequently an artificial achlorhydria; pancreatic secretion, and certainly exposure to pancreatic secretion, may also be inadequate. The stools are light in colour, and may show fatty crystals and meat fibres, but no blood. There is no pain, but there is often discomfort referred to the small bowel area surrounding the navel and occurring almost immediately after food. In a case of this kind recently under my care the patient had once noticed fragments of egg white in the stools within half an hour of their ingestion; X rays showed the stomach to be empty in ten minutes; test-meal showed achlorhydria, and the stools contained soaps, fatty acids, and meat fibre in excess of normal. Dry meals, lying down after the main meals, and the administration of acid (provided there is no persisting evidence of gastric, duodenal, or jejunal ulceration) often give relief, and pancreatin may be helpful.

The serious type is due to the development of a jejuno-colic fistula as the result of jejunal ulceration. In such cases pain, great emaciation, and vomiting may be present in addition to the diarrhœa, and gastric acidity is likely to be high.

Diarrhœa Originating in the Small Bowel.

There is only one important cause of diarrhœa in this group—namely, tuberculous ulceration of the ileum. For this reason diagnosis should seldom be in doubt as (excepting in the far less common variety of localised ileo-cæcal tuberculosis) there is nearly always active coexisting lung disease or abdominal tuberculosis. The frequency of the calls to stool is very variable, and it should, of course, be recognised that ulceration may be present with constipation. Generally the frequency bears some kind of relation to the extent of the disease. A common story is four to six actions daily—a rather higher average figure than in most cases of gastric diarrhœa, but a lower one than obtains in ulcerative lesions of comparable severity in the large bowel. In contradistinction to the gastric group pain is a frequent and troublesome association. It is usually referred to the peri-umbilical and right iliac zones, and tenderness in the right iliac fossa is commonly present. There is the same post-prandial tendency to looseness as in the diarrhœas of gastric origin, and hot soups and fluids are especially disturbing. The stools are soft or semi-fluid, and light in colour. It is rare for macroscopic blood or mucus to be present, but positive results with the benzidine, guaiac, and spectroscopic tests are obtainable. If the ulceration be very extensive, and particularly if there be much involvement of the mesenteric glands causing obstruction to the lymphatic flow, the stools may be copious and chalky-looking and contain excess of fats and soaps, while in virtue of the diarrhœa undigested meat fibres may be present. With appropriate technique tubercle bacilli can also be demonstrated.

Treatment in these cases can only be palliative, but Gull[4] pointed out as long ago as 1855 the importance of avoiding the then common practice of giving cod-liver oil or a diet rich in milk and cream in cases of tuberculous disease in which fat absorption is at fault.

Diarrhœa Originating in Disease of the Colon and Rectum.

This is a most important group, and is more beset with difficulties than either of those to which I have referred. It includes the chronic phases of amœbic and bacillary dysentery, other forms of infective ulceration of the colon of unspecified origin, non-ulcerative types or stages of colitis, malignant ulceration of the colon and rectum, the terminal colitis of Bright's disease, certain spurious forms of colitis and diarrhœa, such as that which is commonly classified as "muco-membranous," and those due to constipation, abuse of purgatives, and excess of douching. In this group more than any other careful rectal examination, direct inspection of the mucosa through a sigmoidoscope, and macroscopic and microscopic examinations of the stools are of importance. It is in this group that serious mistakes are made through omission of simple examinations. It will probably have been within the experience of many of us to discover a rectal carcinoma, perhaps in a patient below the common age, primarily regarded and treated, sometimes for months, as a case of "diarrhœa," "colitis," or "piles." I see two or three such cases every year, and there are other pitfalls; I have, for instance, in the last two years seen three patients who had at some previous date suffered from dysentery or ulcerative colitis, but in whom a carcinoma of the colon had subsequently developed and been missed in spite of careful investigations. The old story of colitis or dysentery had served to lull suspicion instead of rousing it, for there is, I believe, a definitely increased liability to malignancy in persons who have previously suffered from chronic infective ulceration of the large bowel.

In a considerable proportion of all cases of diarrhœa from active colonic or rectal ulceration, from whatever cause, blood, mucus, and sometimes pus will have been observed by the patient himself at some period of his illness. So long as ulceration persists blood will be demonstrable microscopically and chemically, if not macroscopically, for the cells have not, as in bleeding at a higher level, had time to undergo disintegration. Leucocytes much more readily undergo disintegration, and for this reason their presence in large numbers points to a lesion low down in the large bowel or to an abscess discharging thereinto. Goiffon[5] states that albumin in the filtrate from a fæcal emulsion is a reliable index of the presence of active bowel ulceration, but I have not employed the test myself. Pain, both colicky and (if there is extensive inflammation of the wall of the bowel) more continuous, and accompanied by tenderness, is a frequent but not constant association of all ulcerative forms of colitis. It is commonly referred to the lower abdomen, and especially to the region of the descending colon and rectum, and is most in evidence during or after defæcation. The diarrhœa may be continuous or intermittent and, particularly in cases of malignant disease, may alternate with constipation. In an acute phase the evacuations are frequent and small, and consist largely of blood, mucus, and sometimes pus. In the more chronic phases they may be watery and intermixed with fæcal material, the blood and mucus being less conspicuous. With growths low down in the colon and in the rectum the blood may sometimes be so intimately mixed with a watery brown malodorous evacuation as to escape the patient's notice. When not sufficiently obvious on a casual inspection blood and mucus can often be made apparent by gently tilting the bed-pan—a receptacle which should always be employed in preference to others in suspicious cases; the viscid mucous fragments are then seen to slide more slowly across the white field than the fluid elements of the stool. Washing with water may also bring abnormal particles to light.

The Dysenteries.

In the case of the dysenteries it is important to recognise that both varieties (though more rarely that due to *Entamœba histolytica*) may be acquired in this country, and that relapses after periods of good health are common. Of the two the amœbic variety is the more likely to give rise to a chronic mild diarrhœa with little or no pain. The asylum dysenteries have been shown to be generally due to bacillary infections, and Hurst[6] has suggested that a considerable proportion of the sporadic cases formerly classified as "ulcerative colitis" are in reality chronic bacillary dysentery. From the point of view of the morbid changes in the mucosa no distinction can be drawn between chronic bacillary dysentery and chronic "ulcerative colitis," and a certain proportion of cases of the latter show a very remarkable response to treatment with polyvalent anti-dysentery serum. When it is remembered that only a comparatively small proportion of acute bacillary dysenteries give positive cultural results it is no cause for surprise that chronic cases are generally negative from the bacteriological standpoint. This uncertainty in laboratory diagnosis renders a direct visual examination of the diseased surface all the more important. So valuable diagnostically is the appearance of the local lesion that a digression on the application of sigmoidoscopy in all forms of colitis, whether suspected of belonging to a surgical or medical category may, perhaps, be pardoned.

Although, as with other endoscopic instruments, technical difficulties are encountered from time to time, no special manipulative skill is necessary for the use of the sigmoidoscope. It is a simple instrument and, with practice and due care, its employment entails little or no risk. Unless there is ulceration of the anal canal or a concomitant pelvic inflammation its passage—though uncomfortable—is practically painless, and an anæsthetic is seldom necessary and should preferably not be given.

Unless general weakness or special circumstances forbid, the patient should be examined in the knee-elbow position. There should be as little preparation beforehand as possible, and the clearest views are often obtained in patients who have simply been instructed to get up and empty the bowel voluntarily two or three times in the few hours before the examination. Purgatives are best avoided altogether, but simple preliminary lavage may be necessary. A hypodemic of morphine, 20 minutes before the examination, serves to allay anxiety and to lessen peristalsis. After the first few inches are passed the instrument must be guided visually.

In *ulcerative colitis and chronic bacillary dysentery* all phases between a granular mucosa with a tendency to bleed easily and extensive, but usually superficial, ulceration may be seen. The ulcers, except in very severe types, are shallow and their margins are not raised or undermined. The intervening mucosa is never healthy, appearing red, swollen, and easily bleeding. A film of muco-pus frequently covers the ulcerated areas. In cases of long-standing a condition of generalised polyposis may develop.

In the chronic forms of *amœbic dysentery* seen in this country it is rare to find extensive ulceration; but the appearances, though often slight and inconspicuous, may be completely diagnostic. The ulcers are usually quite minute and round and appear as tiny central craters in a small elevation of the mucosa. The craters may be empty or contain a yellow slough, in which case they are not unlike small boils or carbuncles. The intervening mucosa looks healthy. After a few doses of emetine the whole mucosa may become absolutely normal in appearance. I have seen the diagnosis of chronic amœbic diarrhœa made on these appearances in a case in which skilled laboratory investigation completely failed to discover either amœbæ or cysts. The condition responded at once to emetine. In no case, therefore, of possible amœbic diarrhœa can we accept a negative laboratory diagnosis as final unless we have also used our own eyes to inspect the attainable regions of the lower bowel. Thereafter we have still the therapeutic test. It should, of course, be remembered that amœbic infections may involve a higher level; that they have a predilection for the cæcum; and that when we observe healing lower down it does not necessarily imply that it is complete higher up.

The special laboratory investigations in the suspected dysenteries include a search for amœbæ and cysts; cultivations from particles of muco-pus or direct swabbings from an ulcer through the sigmoidoscope; and testing the patient's serum against known bacillary types.

I shall not here embark upon a discussion of the treatment of chronic dysentery and ulcerative colitis beyond saying that treatment should always be instituted as early as possible, and that (whatever symptomatic and local measures are used) it should be as specific as possible, or, in other words, based on as accurate a diagnosis as circumstances will permit. Time lost in palliative measures may seriously prejudice the outlook. Serum or emetine may both be given on a sigmoidoscopic diagnosis without waiting for laboratory reports, just as antidiphtheritic serum is given to cases of "clinically positive" sore-throat. In diarrhœa due to carcinoma coli the stools show the presence of blood and, if low down, of pus cells. They are often very malodorous and fluid. When the accessible part of the bowel appears normal, but there is a clear history of blood and mucus, or these can actually be seen coming down from a higher level with the sigmoidoscope, growth should be strongly suspected. I shall quote a single case in which my own provisional diagnosis was wrong, merely to illustrate the corrective value of sigmoidoscopy and a microscopic examination of the stools.

A man, aged 53, consulted me on account of diarrhœa of one month's duration, associated with some epigastric pain. The evacuations numbered six or seven per diem. He stated that he had had several similar attacks of shorter duration during the previous ten years. His wife stated that he was always inclined to looseness. There was no lower abdominal pain, though he had had pain in the lumbo-sacral region. He used to drink enormous quantities of beer, but had latterly given up beer altogether and admitted only to small quantities of gin and whiskey. His teeth had been extracted on account of bad oral sepsis, and he was wearing a very ill-fitting denture. Appetite was not impaired, but there had been a drop in weight amounting to six pounds in a month. The history of alcoholic excess and dental sepsis; the long-standing history of diarrhœa; the reference of pain to the epigastrium; a red nose, and a negative abdominal and rectal examination suggested to me a diagnosis of chronic gastritis with achlorhydria. However, his age, loss of weight, and a bad family history prompted further investigation. Sigmoïdoscopy revealed a proliferative and ulcerated growth at a point 22 c.cm. above the anus, and on the same day my colleague, Dr. J. H. Ryffel, reported red cells and pus in the fæces, and suggested the probability of carcinoma coli. Test-meal showed a low normal curve of acidity. The patient, who was certainly not very observant, had never noticed blood or mucus in his stools.

Radiography may sometimes be of the greatest value in the diagnosis, and particularly in the localisation of a colonic carcinoma, but *negative radiographic evidence should never be accepted as final.* I have seen one case in which a completely negative report on the transit of barium given by enema was submitted, and in which acute obstruction from an annular carcinoma took place within the ensuing 24 hours. In another non-diarrhœic case a confident negative report from a radiologist—in spite of a suspicious local delay, described as being due to a spasm—resulted in the allaying of clinical suspicions in a case in which clinical history might have justified a laparotomy.

Spurious and Artificial Colonic Diarrhœas.

Under this heading, which includes types not strictly conforming to Roux' definition, I propose to consider muco-membranous colitis or, as it is better called, muco-membranous colic, and those artificial diarrhœas which sometimes accompany chronic constipation and the prolonged abuse of purgatives.

The picture of muco-membranous colic is a familiar one. It occurs in women of a particular nervous type in whom chronic anxiety and depression have developed in relation to the state of their excreta and many other things; they are generally of sallow habit and have dark skins; they suffer much from abdominal pain referred especially to the descending colon, which may be unduly palpable as a hard cord; their evacuations are too frequent and they often say that they have diarrhœa. Strictly speaking, the stools are too fluid only to the extent that they are passed in association with large quantities of coagulated mucus often in the form of long casts. If examined carefully and at a time when purgatives are not being taken, it will generally be found that the fæces are fragmentary and constipated. Blood and pus are absent, and the mucous membrane appears normal or only slightly red through the sigmoidoscope. The condition is really one of spasmodic constipation, and the large quantities of mucus are the result of irritation and over-secretion rather than of actual inflammation. If treatment with purgatives or douches has been carried out over long periods, or there has been much fæcal retention, a true irritative colitis with diarrhœa may be superadded. With chronic rectal constipation or dyschezia, erroneously treated with salts or irritating laxatives, it is not uncommon for small ineffectual fluid stools to be passed, but rectal and abdominal examination will disclose an accumulation of scybala in the lower bowel, and discontinuance of the purgative medicines and the institution of rational hygienic measures should relieve the condition.

DIARRHŒA DUE TO DISEASE OF THE PANCREAS.

Bright[7] was the first in this country to draw attention to the occurrence of fatty diarrhœa in certain cases of carcinoma of the pancreas involving the duodenum. Pancreatic diarrhœa is actually a very rare condition, though mainly on the strength of laboratory reports it has become rather a fashionable diagnosis in certain quarters. The chief feature of the stools in a true pancreatic diarrhœa is the passage of fat in the shape of oil or a fatty coagulum, or of oil which later congeals as a fatty layer. Microscopically fat globules are shown and undigested meat fibres and starch are also present. The diastase test in the urine, or glycosuria may give further evidence of impaired pancreatic function. Carcinoma, calculi, and chronic pancreatitis are among the conditions in which a true pancreatic fatty diarrhœa has been described.

FATTY OR CHYLOUS DIARRHŒA FROM DISEASE OF THE ABSORPTIVE SYSTEM.

There is, however, another important cause of fatty diarrhœa, as Gull[8] originally pointed out, in which the fat is passed intimately mixed with the stools and is largely present as split fats, appearing under the microscope as crystals and soaps. The stools under these conditions are very bulky, in some cases almost incredibly so. They are pultaceous, pale or greyish in colour, greasy and rancid, and they may froth like soap when water is poured upon them. The absorptive apparatus includes the intestinal mucosa and the lacteal tree. Gull recorded the occurrence of fatty stools of this type in tuberculous disease of the mesenteric glands, and I[9] have recently reported similar cases in which in the course of a laparotomy the lacteals were actually seen to be enormously distended with chyle, owing to obstruction by caseous glands in the mesentery. Other conditions in which stools of similar character may be encountered include the so-called cœliac affection in children, tropical sprue, and occasional cases of abdominal malignant disease. In sprue and cœliac disease other symptoms which may accompany the fatty diarrhœa of tabes mesenterica (such as tetany due to the excessive excretion of calcium) are also recorded, and I have, therefore, put forward the suggestion that the diarrhœa in these conditions will possibly be found to be due to obstruction of the lacteals by some other non-tuberculous disease of the mesenteric glands. One of my cases is perhaps worth describing in brief.

A bright-looking and fairly well-nourished girl, aged 23, came under observation on account of chronic diarrhœa and tetany. The stools were enormously bulky, of a porridgy consistency, greyish, and rancid. Under the microscope fatty crystals, soapy fragments, and meat fibres were demonstrated, and a suspicion of pancreatic disease was in consequence entertained. A laparotomy became necessary on account of appendicular symptoms. It was then seen that the lacteals were all greatly distended with chyle, and that this was due to obstruction by caseous glands. Withdrawal of fats from the diet resulted in the passage of formed stools and a cessation of the tetany. There had been a tendency to diarrhœa since infancy, and the tetany had first appeared six years previously, so that without other grave general symptoms or undue abdominal enlargement a condition of tabes mesenterica must have been present for a very long time.

The treatment of all cases of fatty diarrhœa in which faulty absorption is suspected should include rigid fat restriction. It is remarkable what improvement in respect of the diarrhœa, weight, general nutrition, and other secondary symptoms may follow this simple procedure.

SIMPLE DIARRHŒA ACCOMPANYING MESENTERIC GLANDULAR TUBERCULOSIS.

In addition to a true fatty or chylous diarrhœa, we should also recognise a simple form of mild chronic diarrhœa with passage of light-coloured stools, which is among the earliest symptoms in tuberculous disease of the abdominal lymphatic glands. The symptoms may be present long before the abdomen becomes appreciably enlarged or without other classical signs of tabes mesenterica ever appearing. I have seen several cases of this type in the past year in which further investigations strongly supported a diagnosis largely prompted by this symptom. The condition is practically confined to children and young adults. The following is a case in point:—

A small girl, aged 11, was brought to see me on account of attacks of lower abdominal pain. For some time past her mother had noticed that she was having her bowels moved too frequently. The stools were reported as loose and light in colour, and this was confirmed on making a rectal examination. Her mother and teacher had both observed that she easily became tired, and she often went to bed on her own initiative long before her usual bedtime. The pain in the attacks she referred to both iliac fossæ—a rather common reference in these cases. I suggested keeping her under observation at home, with morning, afternoon, and evening temperature records. The five o'clock mouth temperature (the hour at which she often wanted to go to bed) was found to be nearly always 99 or above, and on one occasion it was 100. X ray examination of the thorax showed shadows of numerous small calcified glands at the hila, and considerable peri-hilar infiltration. Rest in bed, with a diet in which fats were kept low, resulted in a steady gain in weight and a cessation of the diarrhœa. The daily swing of temperature steadily diminished. There were no further attacks of abdominal pain. At no period were any of the characteristic signs of tabes mesenterica present.

I do not imagine that the diarrhœa in these cases expresses ileal ulceration, but rather that it signifies agian a fault of absorption due to glandular disease, though of a lesser degree than that encountered in the very occasional cases of fully developed chylous diarrhœa. The diarrhœa of lardaceous disease—now so rarely seen—probably depends in part on faulty absorption due to amyloid changes in the intestinal mucosa.

DIARRHŒA IN CHRONIC CHOLECYSTITIS.

In chronic mild infections of the gall-bladder, persistent or intermittent diarrhœa of a mild grade is a not uncommon complaint. The associated symptoms include epigastric or right subcostal pains and discomforts; a dyspepsia of which nausea and right subscapular or interscapular pain are frequent features; vague general ill-health; a tendency to unexplained spikes of pyrexia, and other manifestations peculiar to chronic infections of the upper gastro-intestinal tract. There is usually tenderness at the gall-bladder point. I am not sure whether the diarrhœa in these cases should be regarded as a reflex diarrhœa akin to the accompanying reflex dyspepsia, or as an expression of the general upper-tract infection, or possibly of the achlorhydria which is found in a certain proportion of the cases. Cultural investigations of the bile obtained through a duodenal tube may support the clinical diagnosis. The treatment is the treatment of cholecystitis. If gall-stones are not suspected and there is no sufficient indication for surgery it should in the first instance comprise general [illegible] and dietary measures, and the administration of biliary antiseptics such as urotropine and [illegible].

DIARRHŒA DUE TO ORGANIC NERVOUS DISEASE.

I do not propose to discuss tabetic diarrhœa. French authors, of whom Timbal[9] mentions several, have described a true diarrhœa in tabes, but I have not personally seen a case. The only one in my experience in which the diagnosis might have been entertained did not conform to Roux's definition; that is [illegible], although the patient—an undoubted tabetic [illegible] small proportion of acute bacillary dysenteries give positive cultural results it is no cause for surprise that chronic cases are generally negative from the bacteriological standpoint. This uncertainty in laboratory diagnosis renders a direct visual examination of the diseased surface all the more important. So valuable diagnostically is the appearance of the local lesion that a digression on the application of sigmoidoscopy in all forms of colitis, whether suspected of belonging to a surgical or medical category may, perhaps, be pardoned.

Although, as with other endoscopic instruments, technical difficulties are encountered from time to time, no special manipulative skill is necessary for the use of the sigmoidoscope. It is a simple instrument and, with practice and due care, its employment entails little or no risk. Unless there is ulceration of the anal canal or a concomitant pelvic inflammation its passage—though uncomfortable—is practically painless, and an anæsthetic is seldom necessary and should preferably not be given.

Unless general weakness or special circumstances forbid, the patient should be examined in the knee-elbow position. There should be as little preparation beforehand as possible, and the clearest views are often obtained in patients who have simply been instructed to get up and empty the bowel voluntarily two or three times in the few hours before the examination. Purgatives are best avoided altogether, but simple preliminary lavage may be necessary. A hypodemic of morphine, 20 minutes before the examination, serves to allay anxiety and to lessen peristalsis. After the first few inches are passed the instrument must be guided visually.

In *ulcerative colitis and chronic bacillary dysentery* all phases between a granular mucosa with a tendency to bleed easily and extensive, but usually superficial, ulceration may be seen. The ulcers, except in very severe types, are shallow and their margins are not raised or undermined. The intervening mucosa is never healthy, appearing red, swollen, and easily bleeding. A film of muco-pus frequently covers the ulcerated areas. In cases of long-standing a condition of generalised polyposis may develop.

In the chronic forms of *amœbic dysentery* seen in this country it is rare to find extensive ulceration; but the appearances, though often slight and inconspicuous, may be completely diagnostic. The ulcers are usually quite minute and round and appear as tiny central craters in a small elevation of the mucosa. The craters may be empty or contain a yellow slough, in which case they are not unlike small boils or carbuncles. The intervening mucosa looks healthy. After a few doses of emetine the whole mucosa may become absolutely normal in appearance. I have seen the diagnosis of chronic amœbic diarrhœa made on these appearances in a case in which skilled laboratory investigation completely failed to discover either amœbæ or cysts. The condition responded at once to emetine. In no case, therefore, of possible amœbic diarrhœa can we accept a negative laboratory diagnosis as final unless we have also used our own eyes to inspect the attainable regions of the lower bowel. Thereafter we have still the therapeutic test. It should, of course, be remembered that amœbic infections may involve a higher level; that they have a predilection for the cæcum; and that when we observe healing lower down it does not necessarily imply that it is complete higher up.

The special laboratory investigations in the suspected dysenteries include a search for amœbæ and cysts; cultivations from particles of muco-pus or direct swabbings from an ulcer through the sigmoidoscope; and testing the patient's serum against known bacillary types.

I shall not here embark upon a discussion of the treatment of chronic dysentery and ulcerative colitis beyond saying that treatment should always be instituted as early as possible, and that (whatever symptomatic and local measures are used) it should be as specific as possible, or, in other words, based on as accurate a diagnosis as circumstances will permit. Time lost in palliative measures may seriously prejudice the outlook. Serum or emetine may both be given on a sigmoidoscopic diagnosis without waiting for laboratory reports, just as antidiphtheritic serum is given to cases of "clinically positive" sore-throat. In diarrhœa due to carcinoma coli the stools show the presence of blood and, if low down, of pus cells. They are often very malodorous and fluid. When the accessible part of the bowel appears normal, but there is a clear history of blood and mucus, or these can actually be seen coming down from a higher level with the sigmoidoscope, growth should be strongly suspected. I shall quote a single case in which my own provisional diagnosis was wrong, merely to illustrate the corrective value of sigmoidoscopy and a microscopic examination of the stools.

A man, aged 53, consulted me on account of diarrhœa of one month's duration, associated with some epigastric pain. The evacuations numbered six or seven per diem. He stated that he had had several similar attacks of shorter duration during the previous ten years. His wife stated that he was always inclined to looseness. There was no lower abdominal pain, though he had had pain in the lumbo-sacral region. He used to drink enormous quantities of beer, but had latterly given up beer altogether and admitted only to small quantities of gin and whiskey. His teeth had been extracted on account of bad oral sepsis, and he was wearing a very ill-fitting denture. Appetite was not impaired, but there had been a drop in weight amounting to six pounds in a month. The history of alcoholic excess and dental sepsis; the long-standing history of diarrhœa; the reference of pain to the epigastrium; a red nose, and a negative abdominal and rectal examination suggested to me a diagnosis of chronic gastritis with achlorhydria. However, his age, loss of weight, and a bad family history prompted further investigation. Sigmoidoscopy revealed a proliferative and ulcerated growth at a point 22 c.cm. above the anus, and on the same day my colleague, Dr. J. H. Ryffel, reported red cells and pus in the fæces, and suggested the probability of carcinoma coli. Test-meal showed a low normal curve of acidity. The patient, who was certainly not very observant, had never noticed blood or mucus in his stools.

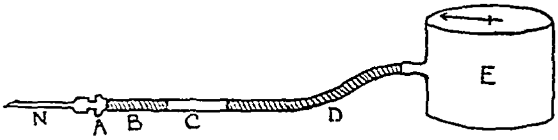
Radiography may sometimes be of the greatest value in the diagnosis, and particularly in the localisation of a colonic carcinoma, but *negative radiographic evidence should never be accepted as final.* I have seen one case in which a completely negative report on the transit of barium given by enema was submitted, and in which acute obstruction from an annular carcinoma took place within the ensuing 24 hours. In another non-diarrhœic case a confident negative report from a radiologist—in spite of a suspicious local delay, described as being due to a spasm—resulted in the allaying of clinical suspicions in a case in which clinical history might have justified a laparotomy.

Spurious and Artificial Colonic Diarrhœas.

Under this heading, which includes types not strictly conforming to Roux' definition, I propose to consider muco-membranous colitis or, as it is better called, muco-membranous colic, and those artificial diarrhœas which sometimes accompany chronic constipation and the prolonged abuse of purgatives.

The picture of muco-membranous colic is a familiar one. It occurs in women of a particular nervous type in whom chronic anxiety and depression have developed in relation to the state of their excreta and many other things; they are generally of sallow habit and have dark skins; they suffer much from abdominal pain referred especially to the descending colon, which may be unduly palpable as a hard cord; their evacuations are too frequent and they often say that they have diarrhœa. Strictly speaking, the stools are too fluid only to the extent that they are passed in association with large quantities of coagulated mucus often in the form of long casts. If examined carefully and at a time when purgatives are not being taken, it will generally be found that the fæces are fragmentary and constipated. Blood and pus are absent, and the mucous membrane appears normal or only slightly red through the sigmoidoscope. The condition is really one of spasmodic constipation, and the large quantities of mucus are the result of placing a manometer in communication with a vein by means of rubber tubing and a hollow needle of adequate bore. The vein usually chosen is the median basilic at the bend of the elbow. Moritz and Tabora,[4] who were the first to employ direct methods clinically, used a manometer containing physiological saline to which a trace of antiseptic was added. The whole apparatus was sterilised, and a broad needle, connected to the manometer by tubing, was inserted into the vein, fluid being allowed to flow into the vein until the manometer showed a constant reading. More recently Italian workers, Castellotti [5] and Corradi,[6] have employed similar methods. It appears to us, however, that these methods, which involve sterilisation of the manometer and saline, and which amount practically to an intravenous transfusion at each observation, are not adapted to routine clinical use.

These objections have been partly overcome by the use of Claude's aneroid manometer, originally devised for determining the pressure of the cerebro-spinal fluid. In this method blood is allowed to flow from the vein through a needle into a rubber tube of 3 mm. bore, the pressure being communicated to the manometer by an intervening column of air. It will be seen from the figure that the apparatus consists of the manometer (E), two pieces of rubber tubing of 3 mm. bore (B and D), separated by a short length of glass tubing (C). An ordinary broad serum needle is attached to the end of the rubber tubing (B) by means of a metal nozzle (A), which fits it accurately. The glass tube acts as a window through which the progress of the column of blood may be watched, and as a means of disconnecting from the manometer that part of the apparatus which requires sterilising. The aneroid manometer is graduated in centimetres of water, giving readings from 0 to 100.



Aneroid manometer. (Supplied by G. Boulitte, Paris.)

Villaret, St. Girons, and Grellety-Bosviel,[7] Leconte and Yacoel [8] in France, and Gazzotti [9] in Italy have made numerous observations by this method both in normal and pathological subjects. As their method appeared suitable for clinical use, we have investigated the results obtained by it in normal individuals under varying conditions as a preliminary to employing it in pathological cases.

Technique (Claude's Method).

The subject lies on his back on a horizontal couch, the head and shoulders being supported by a single pillow. The arm and shoulder must be completely stripped of clothing as the slightest constriction of the limb may artificially raise the venous pressure. It is important that the arm should be comfortably supported and the muscles perfectly relaxed, as tonic muscular contraction impedes the flow of blood along the veins. The tubing (B) carrying the metal nozzle, the glass tubing, and the needle are sterilised in liquid paraffin in a water-bath, and may conveniently be kept ready for use in sterile paraffin. The skin of the arm is sterilised, and the superficial veins at the bend of the elbow are rendered prominent by slight manual compression of the arm. The needle is inserted into a suitable vein in the direction of the blood current and the blood is allowed to flow out for a few seconds till the effects of the stasis have disappeared. The glass tubing having been connected to the manometer, the metal nozzle is now inserted into the needle. As the blood flows from the vein along the tubing the pressure registered by the manometer rises. When the reading becomes constant it is recorded. The nozzle may now be removed from the needle, and after allowing a few drops of blood to escape, it may be replaced and a second reading taken. During the experiment the needle and that part of the tubing containing blood must be kept strictly horizontal and level with the vein, the level of the manometer itself being immaterial. When considerable venous engorgement has been produced in rendering the vein prominent the first reading may be somewhat higher than the second, in which case it should be ignored, and a third reading obtained if possible, the mean of the last two readings being taken. If the needle and tubing are sterilised in liquid paraffin as described, the blood will remain fluid for some time, usually four to five minutes, and at the end of the experiment should drip freely from the needle by gravity.

Position of Arm Relative to Heart Level.—Different observers have placed the arm in different positions, and have taken various points on the chest wall as criteria of heart level. Moritz and Tabora had the arm abducted, slightly bent at the elbow, and pronated, resting on the couch. They adjusted the zero of their manometer to the level of the right auricle, which they took as being 5 cm. below the front of the sternum at the level of the fourth costal cartilage. Under these conditions slight alterations in the position of the arm were not found to affect the reading. Eyster and Hooker, following von Recklinghausen, referred their readings to the mid-point of the antero-posterior diameter of the thorax at the subcostal angle. Lewis corrects his readings to the level of the front of the sternum. The French workers, Villaret and others, place the arm horizontally out from the shoulder in the body plane ("rigoureusement horizontal dans le plan du corps"), by which means, according to them, the hydrostatic factor is eliminated. It appears to us that the exact measurement of the position of a vein relative to the sternum is open to criticism; it is difficult to carry out at the bedside, and owing to the varying shape of the chest in different individuals does not necessarily assure a fixed relation to heart level. It seems equally rational to measure the height of the vein above the level surface on which the subject is lying. For these reasons we have adopted the technique of the French workers, placing the arm horizontal from the shoulder, and supporting it at the elbow on blocks of known height. We find that with the shoulder supported comfortably, the position of the vein relative to the sternum is approximately constant in normal individuals—i.e., 6–8 cm. below the sternum at the angle of Louis or 10 cm. below the subcostal angle. The height of the vein above the couch is usually 11–14 cm. The forearm and wrist must be supported in order to obtain perfect muscular relaxation.

Claude's method has advantages over other direct methods in that the apparatus is portable, the technique simple, the number of parts to be sterilised are few, and there is no necessity to adjust the manometer itself to any particular level, as long as that part of the tubing containing blood is maintained horizontal. Certain criticisms may be offered. Firstly, the manometer must be carefully graduated against a water manometer. We found that, in our instrument, while the higher readings were accurate, the lower readings gave a constant over-estimation, a manometric reading of 15 cm. corresponding to a true pressure of 9 cm. All our readings as given below are therefore corrected from a table constructed by testing Claude's manometer against a water manometer. We can find no mention of correction of the manometric error in the work of the French authors, and this may account for the fact that they obtained somewhat higher readings than we shall record below. Transmission of pressure from fluid to air involves errors due to surface-tension and capillarity. Provided the bore of the tube at the junction of liquid and air is fairly wide—e.g., 3 mm.—this error should not be great, but where the venous pressure is very plained of distressingly frequent and urgent calls to stool, she did not, so far as I could ascertain, pass "too fluid" stools, and more often than not she passed nothing at all. The symptom was, in all probability, due to true rectal or colonic crises. It had been present for many years, but latterly a change in its character had raised the possibility of carcinoma coli. I did not have the opportunity of investigating the matter further.

REFLEX DIARRHŒA.

The following case illustrates a type of diarrhœa which may, I think, legitimately be described under this heading. Cases in which there is an actual appendicular or pelvic abscess should not be included in the same category, for in these the sepsis and peri-rectal inflammation are the more important factors.

A medical man who had had bacillary dysentery during the war started in 1919 to have diarrhœa with frequently recurring exacerbations, associated with much pain of a colicky character, but a complete absence of localising signs. There was pyrexia during the attacks. Various investigations were made with negative result. Several unsatisfactory diagnoses were suggested. No treatment had any effect. A very thorough overhauling in a clinic between attacks was quite unproductive, and in 1922 it was finally decided to perform a laparotomy. A thickened inflamed appendix was removed, which contained about half a cubic centimetre of pus. There has been no return of the attacks since. The appendix was "silent" in so far as the production of symptoms directing attention to itself was concerned, but had produced such definite bowel symptoms as colic and diarrhœa. I would suggest that these symptoms were akin to the reflex gastric symptoms so commonly seen in chronic appendicular disease.

EMOTIONAL DIARRHŒA.

The nervous diarrhœa which I wish more particularly to stress is a functional condition and expresses an anxiety-state, but it is important to recognise that it may develop out of a true irritative or infective diarrhœa. All grades of it are encountered. One individual may have a mere tendency to diarrhœa at the ordinary times of defæcation or on special stressful occasions—as before a viva voce examination; another unfortunate may so far lose confidence in himself and his power to control the activity of his bowel that it becomes impossible for him to go to any social function or to expose himself to any conditions under which self-consciousness is likely to prevail. To have to face the risk of being out of reach of a lavatory on these occasions becomes for him an insufferable anguish. The condition is a visceral neurosis closely akin to nervous bladder frequency. Like stammering and blushing, it is worse on those occasions when it is most important that it should be in abeyance. It is not amenable to wilful control, but rather aggravated thereby. In the treatment sensible explanation and encouragement play an important part, but it is often valuable as a temporary expedient while confidence is being restored to prescribe, in the smallest doses, opium or codeine. When the patient realises that he has a faithful ally in the shape of a minute pill which will carry him through occasions and affairs previously looked upon as insupportable, he has made a decided step towards recovery from his malady, and may happily proceed to the next stage in which it is just as effective to carry the pill in his waistcoat pocket.

FREQUENCY OF THE VARIOUS TYPES OF CHRONIC DIARRHŒA.

With a view to obtaining a rough estimate of the relative frequency of the various forms of chronic diarrhœa seen in this country, I have analysed a recent series of 54 cases. Of these 24 were under my own care. The remainder were patients of Dr. A. F. Hurst, but I had the privilege of seeing most of them with him, and am indebted to him for permission to include them here. The distribution was as follows:—

Diarrhœa of Gastric Origin.—Seventeen cases, or 31 per cent., including six cases of Addison's anæmia, three of alcoholic gastritis, and eight of uncertain pathology. (The high proportion of cases of Addison's anæmia must be regarded as artificial. Without them the remaining cases would show a percentage incidence of 20, and the percentage incidence of other groups would require revision.)

Diarrhœa Originating in the Large Bowel.—Seventeen cases, or 31 per cent., including six cases of ulcerative colitis, four dysenteries, four cases of carcinoma coli, one non-ulcerative colitis, one muco-membranous colic, and one diarrhœa due to constipation.

Diarrhœa Due to Mesenteric Glandular Disease.—Seven cases, or 12 per cent., including three cases of chylous diarrhœa and four of simple diarrhœa, all probably associated with tuberculous glands in the mesentery, though one was possibly a case of cœliac disease.

Diarrhœa Accompanying Cholecystitis.—Five cases, or 9 per cent.

Emotional Diarrhœa.—Four cases, or 7 per cent.

The remaining cases included one each of pancreatic disease (?), gastro-enterostomy, appendicitis, and sprue.

The correctness of the diagnosis cannot be dogmatically asserted in every one of these cases, but all were carefully reviewed, and a large proportion were very thoroughly investigated. Sometimes more than one factor may be at work. I have, for instance, seen a case (not included in this series) in which a relapse of ulcerative colitis was associated with gastritis and achlorhydria, attention being drawn to this by the presence of acne rosacea.

I hope that I have said enough to indicate the great diversity of conditions which may give rise to chronic diarrhœa, and to suggest the methods most likely to be of service in their differentiation. If I have dealt with the question of treatment superficially and briefly it must be my excuse that diagnosis is the beginning and the end of medicine, and the most essential preliminary to rational therapeutics.

In the preparation of the foregoing remarks, which are largely the outcome of casual notes and impressions collected in the past three years, I have been much stimulated by reference to the writings of such old masters of my own school as Bright and Gull; by the perusal of a recent small volume by Prof. Louis Timbal,[9] of Toulouse; and perhaps most of all by my association with Dr. A. F. Hurst, whose knowledge of the subject and whose power of inspiration are equally difficult to measure.

OBSERVATIONS ON THE VENOUS PRESSURE IN NORMAL INDIVIDUALS.

BY D. E. BEDFORD, M.B., B.S. LOND., M.R.C.S. ENG.,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL;

AND

SAMSON WRIGHT, M.B., B.S. LOND., M.R.C.S. ENG.,
SENIOR DEMONSTRATOR OF PHYSIOLOGY, MIDDLESEX HOSPITAL MEDICAL SCHOOL.

(From the Department of Physiology, Middlesex Hospital Medical School.)

To estimate the venous pressure in man two main methods—the indirect and the direct—have been employed. The indirect methods consist in determining the external pressure necessary to produce collapse of a small superficial vein, or the pressure which just prevents refilling of a vein previously emptied by "milking" towards the heart. For details of these methods reference should be made to the papers of von Recklinghausen,[1] Eyster and Hooker,[2] and Sewall.[3] The direct methods consist in accommodate increased volumes of blood without an appreciable increase in internal pressure occurring. This is a point of great practical importance. In seeking to determine increases in venous pressure in heart disease our object is to estimate the degree of venous engorgement. When this is considerable we can easily appreciate it clinically by observing enlargement of the liver and engorgement of the cervical veins. Unless a rise in venous pressure occurs before clinical evidence of venous engorgement is manifest, the determination of venous pressure in cases of heart disease will be of little practical importance. In our own very limited experience of the venous pressure in pathological cases we have not found it raised unless signs of heart failure were present. The French workers, however, maintain that a rise in venous pressure may be the first indication of incipient heart failure. The volume of blood in the veins must also be considered in regard to hydrostatic effects. When the veins are distended at positions below heart level the frictional resistance to the flow of blood will be minimal. On the other hand, at positions above heart level, where the veins are relatively collapsed, the frictional resistance will be maximal owing to the diminished lumen of the vein and the increased velocity of the stream. For these reasons correction of the venous pressure reading to an arbitrary plane is open to objection. It must also be borne in mind that the veins have been shown to contract in response to nervous stimulation, and Henderson[12] has recently attributed considerable importance to the "veno-pressor" mechanism in regulating the volume of venous blood and the venous return to the heart.

Relation of Venous to Arterial Pressure.

According to Villaret and his co-workers, the venous pressure, in normal subjects, in centimetres of water, approximates very closely to the systolic arterial pressure expressed in centimetres of mercury. They attach great importance to this relationship, and are prepared on the basis of the systolic blood-pressure reading in any patient to state what his physiological venous pressure should be, regarding any appreciable variation from this figure as pathological. Thus in certain cases of arterio-sclerosis and hypertension they consider the venous pressure subnormal where it is below the figure demanded by their formula. In all our observations we have recorded the systolic and diastolic pressures, and we have been unable to find any strict relationship between arterial and venous pressures. Thus, in four subjects in whom the systolic B.P. was 135 mm. Hg, the venous pressure readings were 18, 11, 9, and 7 cm. H_2O respectively, and in four subjects with a systolic B.P. of 140 mm. Hg the venous pressure readings were 14·5, 12·5, 11·5, and 9 cm. H_2O.

Venous pressure is dependent on capillary pressure rather than arterial, and capillary pressure is regulated by the condition of the arterioles. We have investigated the effect on the venous pressure of dilating the arterioles with amyl nitrite in six subjects. In all cases the venous pressure rose definitely by several cm. H_2O, the rise running approximately parallel to the rise in pulse-rate. An example of the effect of inhaling 3 minims of amyl nitrite is given below:—

Pulse-rate at 10-sec. intervals.	Venous pressure.	Pulse-rate at 10-sec. intervals.	Venous pressure.
90 ..	6·5	138 ..	9·0
90 ..	6·5	132 ..	9·5
102 ..	6·5	120 ..	10·0
126 ..	7·0	87 ..	10·0
126 ..	—	A* ..	6·5

A* = Reconnect after short interval.

Effect of Respiration on Venous Pressure.

In normal persons respiratory variations in pressure were not observed in the arm veins. In a pathological case where the venous pressure was 30 cm. H_2O, we observed oscillations of ½–1 cm. Excessive ventilation in normal subjects was found to lower the venous pressure by 1–3 cm. H_2O. If intrathoracic pressure is raised by the subject taking a deep inspiration and holding it for as long as possible, a considerable rise in venous pressure can be produced, the degree of rise depending on the depth of the inspiration and the duration of the apnœa.

An example is given below:—

Observation 38. (B.P. 160/70.)

Initial pressure 7 cm. H_2O, rose to 8·5 cm. H_2O.
On holding breath, rose to 25 cm. H_2O.
On releasing breath, fell to 13·5 cm. H_2O.
Final reading 9 cm. H_2O.

We have obtained a rise in pressure by this method in all subjects, and find it a useful means of proving free communication between vein and manometer.

Effect of Exercise on the Venous Pressure.

In six subjects the venous pressure was taken after fairly severe exertion. Care was taken to employ the minimum compression of the arm before inserting the needle into a vein, and the blood was allowed to escape freely before connecting the needle to the manometer. The readings obtained varied from 9·5 to 19·5 cm. H_2O, and in all cases a definite fall was observed after a few minutes, the average fall being 5 cm.

We conclude that a rise of peripheral venous pressure occurs during exercise, which is in agreement with the findings of Sewall and Gazzotti. This rise may be dependent on a raised intra-auricular pressure resulting from increased venous return, or on arteriolar relaxation in the active muscles producing an increased capillary pressure, or on a combination of these two factors.

Summary.

1. The pressure in the arm veins in normal individuals has been investigated by Claude's manometer according to the technique of Villaret, St. Girons, and Grellety-Bosviel. With the subject recumbent and the arm horizontal the readings obtained were between 5 and 15 cm. H_2O in 90 per cent. of cases. Less constant results were obtained than those recorded by other workers with this method.

2. This method involves errors which probably render the lower readings unreliable, but should prove sufficiently accurate for detecting pathological increases in venous pressure. No reading under 15 cm. H_2O obtained by this method should be regarded as pathological. More accurate determination of low venous pressure is possible if the author's modification is employed.

3. The factors responsible for the normal peripheral venous pressure are discussed.

We have to thank Dr. R. A. Young and Dr. J. Strickland Goodall for kindly allowing us to make observations on patients under their care.

small—e.g., below 5 cm. H_2O—the error may be sufficient to render the reading of little value. A certain error will also occur owing to frictional resistance to the flow of blood through the needle. For these reasons we are not satisfied with the reliability of the lower readings obtained by this method. These errors may be largely overcome by the introduction of a pressure bulb connected by means of a T-piece to the rubber tubing (D), near the manometer. An ordinary 20 c.cm. record syringe fixed to the manometer stand is satisfactory. By regulating the pressure in the air column by means of the pressure bulb, the blood is first allowed to reach the glass tube and then the pressures noted when the column of blood just advances, and when it just reverses and moves towards the vein. The mean of these two readings is taken as the venous pressure. In using this modification an ordinary water manometer may be substituted for the anercid.

Normal Venous Pressure.—We give below the readings obtained by Claude's method in 34 healthy medical students who kindly volunteered to help us in this work.

Pressure in cm. H_2O.	Number of cases.
5 or under	3
5–10	19
10–15	11
15–20	1

It will be seen that over 50 per cent. gave readings from 5–10 cm. H_2O, and approximately 90 per cent. between 5–15 cm. H_2O. If we include certain cases in which the pressure was determined after exercise and allowed to fall to normal, and cases in which we used the modified technique described, a pressure of 5–15 cm. H_2O was obtained in 41 out of 47 cases. The normal venous pressures recorded by other observers are as follows:—

Observer.	Method.	Venous pressure (cm. H_2O).
Frank and Rey ..	Indirect	1–6
Eyster and Hooker ..	,, ...	5–10
Moritz and Tabora ..	Direct	4–8*
Castellotti	,, ...	4–7
Corradi	,, ...	8–13
Villaret and others ..	Claude's man	12–13
Gazzotti	,, ...	13–14

*Extremes 1–9.

Although Claude's method appears to give higher results than other direct methods, it must be borne in mind that if these figures are corrected to the plane of heart level adopted by Moritz and Tabora they would be lower.

Factors Determining Normal Pressure in Peripheral Veins.

It must be emphasised that in measuring the internal pressure in a peripheral vein we are not recording the pressure in the right auricle, even when the vein is carefully placed at heart level. Intra-auricular pressure is said always to be negative, while in any vein outside the thorax a positive pressure is invariably present unless the vein is completely collapsed.

The factors determining the normal pressure in the peripheral veins may be briefly considered as follows: 1. The *vis a tergo* or the capillary pressure. 2. The *vis a fronte* or the negative intra-auricular pressure. 3. The hydrostatic relationship of the vein to the heart. 4. The volume of blood in the veins.

1. *The Vis a Tergo.*—The capillary pressure depends indirectly on the arterial pressure maintained by the left ventricle, and is regulated by the arterioles and possibly by the capillaries themselves. Krogh[10] finds that the capillary pressure is relatively low and varies with the hydrostatic pressure. At and above heart level it remains constant at approximately 4·5 cm. H_2O, while below heart level it is 4·5 plus the hydrostatic pressure. Lewis,[11] from observations on the cutaneous "white line," concludes that the capillaries are capable of exerting a contractile force equal to 50–100 mm. Hg—that is, up to 135 cm. H_2O—and in this way capillary dilatation is avoided at high hydrostatic pressures.

2. *Vis a Fronte.*—This consists in the suction action due to the negative intrathoracic pressure maintained by the elastic recoil of the lungs. This negative pressure will increase during inspiration and decrease during expiration, and normally varies from 8–12 cm. H_2O. Any permanent increase in intra-auricular pressure must ultimately produce a corresponding increase in pressure in the peripheral veins, but owing to the presence of valves it will take an appreciable time for this increase to traverse the gradient from heart to periphery. Thus in normal individuals we have seldom observed respiratory variations in pressure in the arm veins.

3. *Hydrostatic Effect.*—If the veins were a series of rigid tubes without valves the pressure at any point would be directly proportional to the position of that point relative to the heart. As, however, the veins are collapsible tubes freely supplied with valves, simple physical laws may not be too closely applicable. It was noticed by von Recklinghausen, and has been confirmed since, that, in the veins of the foot the pressure falls considerably short of the theoretical hydrostatic pressure. This has been attributed to the "venous pump" mechanism, which is twofold, peripheral and abdominal. Owing to the arrangement of the valves in the peripheral veins muscular contraction will tend to force blood towards the heart. As each segment of vein included between two sets of valves is a potential pump, compression of any segment expels the contents into the more proximal segments. Each time the diaphragm descends with inspiration the blood in the great abdominal veins is driven into the thorax, this force pump action being aided by the increased negative pressure in the thorax during inspiration. Thus the veins in the lower limbs are protected from excessive hydrostatic pressures which would otherwise be produced by the erect posture. It is obvious from these considerations that under normal conditions the peripheral venous pressure must be constantly varying, and it is open to question how far we can use an arm vein as a manometer for the general venous pressure when the arm is kept flaccid at a fixed level. We have studied the effects of altering the level of the arm on the venous pressure as determined by Claude's manometer. Certain practical difficulties arise; it is not easy to keep the muscles relaxed while changing the position of the arm, nor to maintain the needle and tubing in the correct plane. As a result of our observations we can say that invariably raising the arm from the horizontal lowers the pressure, while lowering the arm raises the pressure. We have not been able to satisfy ourselves that the theoretical hydrostatic difference is always realised, but it is possible that we were unable to allow sufficient time for the pressure to stabilise at the new level. On lowering the arm the rise in pressure may exceed the hydrostatic change. We record two examples:—

Observation 64.

Vein 8 cm. below sternum—V.P. = 10 cm. H_2O.
On lowering vein to 19 cm. below sternum—V.P. = 26 cm. H_2O.

Observation 65.

Vein 18 cm. below sternum—V.P. = 34 cm. H_2O.
On raising vein to 5 cm. below sternum—V.P. = 15·5 cm. H_2O.

When a vein is above heart level it does not completely collapse as can be readily verified, and we have recorded positive pressures 5 cm. above sternum level. It seems possible that at positions above heart level the principles which Krogh has applied to the capillary pressure may also be applied to the venous pressure.

4. *Volume of Blood in the Veins.*—It is usually stated that the veins, being widely distensible, can

Expt. 4.—A rabbit which was running a steady titre of 1/2560 to *B. enteritidis* (Gaertner), as a result of injections of killed cultures of this organism given some months previously, was injected intravenously with 0·5 c.cm. of a broth emulsion of a culture of *B. tuberculosis* (bovine). The seventh day after the injection the temperature rose, and on the ninth day it reached 106° F. The animal was obviously ill and died the seventeenth day after the injection. The titre was tested every two or three days, and it remained steady throughout. This experiment was repeated on another rabbit, which lived for four weeks, and the result was similar.

Thus the severe constitutional disturbances which occurred in these two experiments seemed to have no effect on a steady agglutination titre. This result was expected in view of the work of Topley, Imrie, and Platts,[5] who have reported the results of various repeated agglutination tests on inoculated subjects suffering from pyrexia due to various causes other than enteric.

Summary.

Various non-specific antigens were used in an attempt to influence a steady agglutination titre in rabbits. The only instance in which the titre was appreciably affected was when the non-specific antigen bore close serological relationship to the specific one.

A steady agglutination titre remained unaffected by severe constitutional disturbances occurring as the result of infections artificially produced.

These results are evidence in support of the reliability of the repeated agglutination method as a means of diagnosis of enteric in the inoculated subject.

In conclusion, I should like to thank Dr. H. Fielden for his kind help in immunising the rabbits, and Dr. A. R. Berrie for his assistance throughout.

GLANDULAR ACTIVITY IN THE HUMAN FŒTUS.

BY M. F. LUCAS KEENE, M.B., B.S. LOND.,
UNIVERSITY READER IN ANATOMY AT THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN;
AND
EVELYN E. HEWER, D.Sc. LOND.,
LECTURER IN HISTOLOGY AT THE SAME SCHOOL.

IT is well known that the function of certain organs becomes established before birth, but the date at which they first become active is still in many cases obscure. It is not always easy to determine whether a gland or organ is functionally active or not, and, moreover, the elucidation of the problems connected with such activity in the fœtus is rendered the more difficult in that an organ may play a part during development different from that which it does in the adult; further, the transition from one function to the other is probably gradual. It must also be remembered that demonstration of the presence of a secretion in a gland does not of necessity mean that the gland is functionally active, neither does the apparent absence of secretion always indicate the reverse. It is only by examining the evidence obtained from all sources that it is possible to reach conclusions as to the activity of an organ. Although our observations are as yet incomplete, some interesting data have been collected which throw light on this subject, and which seem worth recording.

The glands may be conveniently divided into those belonging to (*a*) the excretory system, (*b*) the alimentary system, and (*c*) the ductless system.

Excretory System.

(1) *Kidney.*—It has long been recognised that the kidney is functional at birth, but the time when it first becomes active has hitherto been very obscure.

(*a*) *Histological Evidence.*—We have recently reported [1] the results of histological investigation of this point. A staining method was devised whereby differences in the H-ion concentration of the cells could be detected as shown by the differential staining of the cytoplasm in the various parts of the tubule. Staining with Scott's hæmatoxylin and Biebrich scarlet following formol-acetic-Muller fixation caused the cells of the convoluted tubules to appear a bright salmon-pink (acid reaction), whereas those of the straight tubules took on a pinkish-purple colour (alkaline reaction). The kidneys of fresh fœtuses of all ages were examined by this method, and the differential staining was obtained in all fœtuses from 12 weeks maturity upwards, but not at 9 weeks or 8 weeks. From the observations of Trevan [2] it would appear that NaH_2PO_4 is specifically excreted by the tubule cells, and it is probable therefore that the first appearance of the staining reaction in these cells depends on the beginning of such excretion. We conclude that the fœtal kidney is certainly functioning by the twelfth week of development, and quite probably as early as the tenth week.

Further histological evidence is forthcoming in that many glomeruli, capsules, and tubules are well developed by 6–7 weeks. The epithelium of Bowman's capsule is found to be cubical in the more newly-formed glomeruli near the surface, whereas in the deeper glomeruli it is flattened even in specimens of 11 weeks. Is it possible that this indicates the presence of fluid in the capsule and tubule even at this early age?

(*b*) *Chemical Evidence.*—A small quantity of urine was obtained from a full-term fœtus, and tested for kreatinin; it was found to contain 0·0779 g. per 100 c.cm. We were fortunate in securing two samples of fresh amniotic fluid, which, in view of its possible excretory function, were tested for urinary constituents. Analysis gave the following results:—

Per 100 c.cm.	Full-term.	32 weeks.
Urea	0·004 g.	0·156 g.
NH_3	0·023 g.	0·0075 g.
Albumin	Not tested.	0·25 g.
Spec. gravity ..	,,	1008
Kreatinin	,,	0·01 g.
Cl', SO_4'', PO_4'' ..	,,	All present.
Uric acid	,,	Absent.
Bile salts	,,	Absent.

(2) *Liver.*—The excretory function of the liver appears to be established early, as well-formed bile-ducts are present in the 12-week fœtus. Pigment can be seen in the intestinal contents at an even earlier date.

Alimentary System.

The various digestive enzymes were tested for * at different stages of development. In the 16-week fœtus pepsin is present in the gastric mucosa, and the pancreas contains both trypsin and trypsinogen, whereas pancreatic lipase and amylase are absent, and no intestinal enzymes are present. By the twenty-fourth week pancreatic amylase can be detected and the trypsinogen has greatly increased in amount. At 32 weeks intestinal enzymes are still absent, but pancreatic lipase is now present in small amount. At full term active trypsin and trypsinogen are both present in the pancreas; the intestinal enzymes have not as yet been tested for. It is remarkable that no HCl has been found in the stomach, even at full term, although pepsin appears as early as the sixteenth week. Mucin is evidently produced early as fully developed goblet cells are present in the intestine, at 8 weeks.

The Ductless System.

(1) *Pituitary.*—The pituitary of an 11-week fœtus shows well-marked histological differentiation and the pars anterior is extremely vascular. The cells of this part show a definite vesicular arrangement and some acidophil colloid-like material is sometimes present.

---

* We are indebted to Miss D. Woodman, B.Sc., for the carrying out of the enzyme tests.

A NOTE ON THE EFFECT OF INOCULATION OF HETEROLOGOUS ANTIGENS

ON A STEADY AGGLUTINATION TITRE, WITH REFERENCE TO THE DIAGNOSIS OF ENTERIC IN INOCULATED SUBJECTS.

By A. B. ROSHER, M.R.C.S., L.R.C.P., D.P.H.,
CLINICAL PATHOLOGIST, INSTITUTE OF PATHOLOGY, CHARING CROSS HOSPITAL.

The diagnosis of enteric fever on the result of a single agglutination test is no longer considered reliable unless certain conditions are fulfilled. This is due to the fact that there is a fairly large percentage of the population[1] who agglutinate one or more of the various members of this group of micro-organisms, either naturally or as the result of protective inoculation.

In order to establish a diagnosis with any degree of certainty, it is necessary to employ the method of repeated agglutination tests, and thus demonstrate that well-marked fluctuation in agglutination titre which is considered characteristic of enteric infections. During the war a certain amount of evidence accumulated in favour of the reliability of this method of diagnosis, but from some quarters it was subjected to considerable adverse criticism. Garrow[2] in 1920 called attention to an early paper by Dreyer and Walker[3] on the production of immune substances, in which they found that *B. coli* agglutinins produced in rabbits by inoculations of *B. coli* vaccine could be increased by the injection of killed cultures of staphylococci or streptococci or the bacillus of Friedländer. On theoretical grounds, Garrow assumed then, with a considerable degree of justification, that infections which have no relationship to enteric might sometimes increase the production of specific agglutinins in the immunised subject, thereby giving rise to errors in diagnosis by this method. If this non-specific stimulation of agglutinins were at all gross, and were to occur with any frequency, it would in all probability destroy the value of the repeated agglutination method as a means of diagnosis, and the object of this investigation is to see to what extent it is possible to influence a steady agglutination titre in rabbits by the injection of non-specific antigens.

Technique.—Record of Experiments and Commentary.

Dreyer's technique has been used, and the tubes were incubated for two hours at 55° C. The dilutions were put up in geometrical series, starting at 1/20 and doubling the dilution in each succeeding tube, and the last tube to show any agglutination visible to the naked eye was taken as the end-point.

Expt. 1.—As the result of an intraperitoneal inoculation of *B. coli* vaccine into a rabbit, agglutinins to this organism were formed. The sixteenth day after the injection the titre was 1/640, and by the twenty-first day it had fallen to 1/80. Two and six days later the titre was exactly the same, and therefore had apparently become steady. The animal was then given 3 c.cm. of a 24 hours' broth culture of *Staphylococcus aureus*, killed by heating for half an hour at 60° C., into the peritoneal cavity. The serum was tested on the first, second, third, fourth, fifth, sixth, seventh, eighth, and eleventh day after this inoculation, and the titre in each case was 1/80. The titre therefore remained unaffected by the non-specific inoculation.

This experiment is to all intents and purposes an exact replica of one of Dreyer and Walker's experiments, in which they demonstrated a 250 per cent. fluctuation occurring the third day after the staphylococcal injection. The only important difference in technique is the fact that their sera were all stored on ice until the end of the experiment and then tested, whereas in this case the titres were ascertained a few hours after the blood was drawn. It is true they were putting up their dilutions in an arithmetical series and therefore would be more likely to detect slight fluctuations in titre, but an increase of 200 per cent. or more would be easily established when using geometrically increasing dilutions; and furthermore, unless the fluctuation reaches this magnitude, it is not considered of diagnostic importance when carrying out repeated tests. This experiment was then repeated (on another rabbit) using 1 c.cm. of a thick emulsion of sheep's red corpuscles for the non-specific injection. The hæmolytic titre rose to 1/40,000, but the agglutinin titre remained steady. If one could raise a titre 200 per cent. or more by a single non-specific injection, one would expect a larger response than this by continuing the process and giving increasing doses, and therefore a rabbit with a steady agglutination titre to *B. paratyphosus* A was given many massive doses of non-specific antigens. The result will be seen in the following experiment:—

Expt. 2.—The agglutination titre of a rabbit's serum to *B. paratyphosus* A was 1/640 eight months after intravenous inoculation of a vaccine prepared from this micro-organism. It then received 11 doses of non-specific vaccine as stated below. The doses were given intravenously with an interval of seven to ten days between the injections.

No. of injection.	Rosenow's vaccine.	Gonococcal vaccine (millions).	*B. coli* vaccine.
Dose 1	= 0·25 c.cm.	+ 500	Nil.
,, 2	= 0·5 c.cm.	+ 500	,,

,, ,, 2	750 ,,
,, ,, 3	500 ,,
,, ,, 4	1250 ,,
Streptococcus (*hæmolyticus*)	1000 ,,
B. influenzæ	500 ,,
Staphylococcus aureus	500 ,,

The animal's serum was tested every four to five days, and in no case showed more than 100 per cent. fluctuation in titre. The fourth and fifth days after the last injection of these massive doses of vaccine, the titre to *B. paratyphosus* A was 1/1280—i.e., 100 per cent. higher than it was before the non-specific inoculations were started.

Dreyer and Walker have noted that the repeated withdrawal of blood tends to raise an agglutinin titre, and therefore it is quite possible to explain a slight increase of this nature on this basis. An experiment was then tried to see if the injection of an organism such as *B. paratyphosus* B would raise a steady titre to *B. typhosus*, as these two organisms are nearer in relationship to each other than *B. coli* and *Staphylococcus aureus*, which have nothing in common. The result was entirely negative, and it was only when two organisms having very close serological relationship such as *B. paratyphosus* C and *B. paratyphosus* B were used, for the primary and secondary inoculations respectively that the primary titre was carried up. In this case the titre to *B. paratyphosus* C was raised from 1/320 to 1/5120 in seven days as a result of the inoculation of *B. paratyphosus* B. In view of the results obtained by Andrewes[4] (1922) it may be noted that the bacterial suspensions employed in this experiment had not been differentiated as specific or non-specific.

Thus it is apparent that with this exception it was found impossible to produce anything more than a slight fluctuation (quite within the margin of experimental error allowed for these tests) in a steady agglutination titre by the injection of killed non-specific antigens. It was then thought advisable to see whether severe, constitutional disturbances would have any effect on a steady titre.

Expt. 3.—A rabbit was immunised to *B. paratyphosus* A and four months later the titre of its serum to this organism was 1/320. It was then injected intravenously with 1/20 c.cm. of a living broth culture of *Pasteurella muris*. The temperature shot up to 107° F. the day after the injection, and the following day it was 100° F. The third day after the injection the animal died after an extremely acute infection. The titre was tested daily, and did not show more than 100 per cent. fluctuation.

A CASE OF “CONGENITAL” OCCLUSION OF THE COMMON HEPATIC DUCT

IN A TWIN BABY,

WITH AN INDIRECT VAN DEN BERGH REACTION.

By W. M. FELDMAN, M.D. Lond., F.R.S. Edin.,
PHYSICIAN TO ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, PLAISTOW.

With the Assistance of

Miriam A. Lawson, M.R.C.S., L.R.C.P.,
HOUSE PHYSICIAN TO THE HOSPITAL.

Cases of obstruction of the bile-passages in young infants are sufficiently rare to deserve recording, but the case reported here is probably unique in the literature because it presents two features which have important bearings on the pathogenesis of jaundice as well as on the ætiology of the obliteration of the bile-ducts in infants.

T. W. D., a male infant, 8 weeks old, was brought to the out-patient department on Jan. 11th, 1924, on account of jaundice, and was admitted under my care.

History.—The child was one of binovular twins. His birth-weight was 7½ lb. He was breast-fed for two weeks, but was then weaned on account of vomiting and was put on dried milk. His colour was perfectly normal until he was 3 weeks old, when he began to be yellow. The umbilicus had been discharging at this time. The jaundice then increased gradually until the child became bright yellow all over, when he was brought to hospital. He vomited a little after each feed and bled from the nose when he screamed. The stools had been of putty colour and hard since the onset of jaundice. The twin sister was quite healthy. The mother had nine other children (all of whom, with the exception of one who died of meningitis, are alive and well) and never had miscarriages or abortions. The father had been treated for “purpura.”

Progress.—On admission, the child was well nourished and weighed 10 lb. 5 oz. The jaundice was very pronounced and the urine deeply coloured. It, as well as the blood, contained an excess of bile-pigment, but the stools were acholic. Constipation was marked. There was a small umbilical hernia and a few palpable glands in neck and groin. The lower margin of the liver reached to about 2 inches below the costal margin, but the spleen was not enlarged. There were no signs of congenital syphilis and the Wassermann reaction was negative. The fragility of the red blood corpuscles was not increased. The van den Bergh reaction was carried out by Dr. Arthur Davies, pathologist to the hospital, who reported that “the blood serum gave a perfect indirect reaction,” pointing to non-obstructive jaundice. The child seemed to progress favourably for the first ten days, taking its feeds of 3 oz. of equal parts of cow's milk and water with only occasional vomiting, and its temperature kept normal except for an occasional evening rise to 99° F. On the eighteenth day the infant became suddenly worse, the temperature rose to 102° and remained high for about five days, when it began to fall gradually till the day of death, on Feb. 5th—i.e., 25 days after admission—from emaciation and collapse. The highest temperature was 103·2°. Its weight at death was 8 lb.

Post-Mortem.—The liver was large and greenish-yellow, firm in consistency and smooth on the surface. There was no naked-eye evidence of fibrosis. There was no gall-bladder or cystic duct. The two hepatic ducts were seen, but appeared to be small in size and to have thicker walls than normally. The viscera were examined for the common bile-duct and its opening into the duodenum, without success. All the other viscera, spleen, &c., appeared to be normal.

It was quite clear from the history, the choluria, and the fæcal acholia, that the case was not one of ordinary, so-called physiological icterus neonatorum. The absence of jaundice in the other children or near relatives showed that it was not a case of the grave type of familial jaundice. The absence of any history of syphilis in the parents, the health record of the patient's numerous sisters and brothers, and the negative Wassermann reaction in the patient's serum practically certainly excluded syphilitic hepatitis. Septic jaundice could similarly be excluded, for although there had been a discharge from the navel there were no signs suggesting direct relationship between it and the jaundice. Buhl's disease (acute fatty degeneration of the newborn) and Winckel's disease (cyanosis afebrilis icterica cum hæmoglobinuria) could also be excluded. The history of “purpura” in the father suggested hæmolytic or acholuric family jaundice, but the urine and fæces and the normal fragility of the red cells excluded this. The diagnosis, therefore, rested between obstructive jaundice due to obliteration of the bile-passages or possibly gall-stones,[1] and the so-called non-obstructive or catarrhal jaundice. The late onset did not exclude “congenital” obliteration, but it made one incline rather to “catarrhal” jaundice, which though extremely rare in infants has been described by Raudnitz[2] and Lovett Morse,[3] and the result of the van den Bergh reaction was, according to the latest theory of jaundice, certain evidence in favour of catarrhal or non-obstructive jaundice. The post-mortem findings, however, showed that this was misleading. This is a point of very great clinical interest and importance. In the theory of jaundice suggested by McNee[4] it is claimed that bilirubin is not formed by the polygonal glandular liver cells, but in the reticulo-endothelial cells of the spleen and Kupffer cells of the liver, and in its passage through the glandular cells of the liver to the bile-passages is modified in some way. Bilirubin so modified—e.g., gall-bladder bile—gives the direct van den Bergh reaction. Bilirubin that has not passed through the glandular liver cells—e.g., in hæmorrhagic effusions—gives an indirect reaction only. Clinical observations by various authorities, including McNee[5] have so far agreed that in all cases of complete obstruction in adults a direct reaction is always obtained, whilst in true hæmolytic jaundice, it is always of the indirect type. It is further claimed that in cases where there is both damage to the polygonal liver cells and obstruction in the bile-passages, both the direct and indirect reactions have been obtained—biphasic reaction. In the case recorded above one should theoretically have expected either a direct reaction, or possibly a biphasic one. The fact that a definitely indirect reaction was obtained shows clearly that the test, as a clinical method of differentiation between the obstructive and non-obstructive types of jaundice, is not as reliable as has been claimed.

Concerning the pathogenesis of obliteration of the bile-ducts in infants, on embryological grounds, it cannot be a true aphasia or lack of development, since the bile-ducts and liver develop as an outgrowth from the duodenum and hence there can be no liver without a bile-duct. The theory put forward by Rolleston[6] is that the obliteration is due to “inflammation of the biliary passages, the result of prenatal absorption by the fœtus of toxins coming from the mother.” However plausible this theory may be in the cases of obliteration hitherto recorded it is untenable here, because the fellow twin is perfectly normal. My own view is that the obliteration in this, and probably in all the other cases in which the jaundice is not evident at birth or within a couple of days after birth, is due to *postnatal* toxic absorption from the navel. It is for this reason that I have in the title of this paper modified the word *congenital* by means of inverted commas. I suggest that in future the word *congenital* be omitted altogether when cases of occlusion of the bile-ducts in infants are described.

I am indebted to Dr. Arthur Davies for the biochemical investigations.

At this age most of the cells are basophil, but acidophil cells can already be distinguished; as development proceeds the latter become much more numerous and by 30 weeks they present under a low magnification a striking picture when stained with Biebrich scarlet. At full term all parts of the gland appear fully developed.

We have tested for the presence of active principles, using the melanophore reaction described by Hogben and Winton.[3] The test is carried out as follows: An extract of the whole fresh gland is made in 0·6 per cent. NaCl and the resulting solution injected subcutaneously into a yellow frog; expansion of the skin melanophores and consequent darkening of the frog's skin indicates the presence of pituitary hormone. This reaction was obtained quite markedly, even with the gland of a fœtus of 8 weeks.

(2) *Thyroid.*—Although the chief functions of this gland are well known it is extremely difficult to devise a method whereby to test for the active principles of the organ outside the body when only very small quantities of material are available. The evidence that we can put forward for the gland is therefore almost entirely histological.

(*a*) *Histological Evidence.*—Functional activity in the thyroid is regarded as being shown by the following features: (1) A vesicular epithelium of cubical or columnar cells, granular, and with a large spherical nucleus; (2) a rich blood supply; (3) the presence of lightly staining acidophil colloid, usually showing vacuolation at the periphery. The full-time fœtal thyroid appears to be actively secreting as judged by these points. It is, however, not uncommon to find signs of post-mortem change even in apparently fresh material, the change in some cases attaining to complete desquamation of the vesicular epithelium and disappearance of colloid. From an examination of the history of these cases it has been found that there has been almost always either a very prolonged labour or a condition of maternal toxæmia. It is known that the thyroid is stimulated by alimentary toxæmia (McCarrison),[8] and it may be that the toxic condition of the mother or the extreme congestion of the fœtus caused by prolonged labour may induce an unstable condition in the fœtal thyroid, so that post-mortem changes set in much more rapidly than usual. An examination of younger fœtal thyroids shows that some material, staining like the colloid, is present in the vesicles even at 11 weeks maturity; the vesicles are small, but the cells appear to be actively secreting, and the gland is extremely vascular.

(*b*) *Other Evidence.*—The presence of iodine as indicating the active principle of the gland, has been shown by Fenger [4] to be present at least during the last three months of intra-uterine life. From examination of the staining of the colloid, Livini [5] states that the thyroid cells become active when the embryo is between 62 and 66 mm. in length. We have endeavoured, hitherto unsuccessfully, to devise a method of testing for the thyroid active principles based upon their effect on metabolic rate, since the method of Gudernatsch of feeding tadpoles is not here practically applicable.

(3) *Parathyroid.*—Werelius [6] states that this gland probably does not function before birth, but in this investigation we have found the gland at 20 weeks presenting an appearance similar to that of the fully developed gland, with granular cells arranged as in the adult, and a rich vascular supply with large perivascular lymphatics.

(4) *Thymus.*—In the fœtus of 8 weeks cortex and medulla are already distinguishable, and chromaphobe epithelial cells (the precursors of Hassall's corpuscles) can be seen. At 12 weeks typical Hassall's corpuscles are found, although very few in number. The function of this gland is still a matter of controversy.

(5) *Suprarenals.*—The interpretation of the histological appearance of the gland at various stages of its development is by no means easy, and it is hoped to make a separate communication on this point at an early date. Meanwhile the following observations are of interest.

(*a*) *Chromaphil Reaction.*—The gland was tested for the presence of chromaphil material by Ogata's[7] potassium bichromate method, and also by the routine formol-acetic-Muller method of fixation. We have not yet obtained this reaction at all satisfactorily with early fœtal suprarenal glands or fœtal sympathetic ganglia, although a few cells usually give the reaction even at 25 weeks.

(*b*) *Lipoid Reaction.*—Sections of the formol fixed gland were tested for the presence of lipoids by the Sudan III. method of staining: (1) Medulla: At 16 weeks a few cells are found to contain lipoid, and from 32 weeks up to full term and for at least 36 weeks after birth there is a well-marked staining of the medulla cells. This reaction was absent in two cases of anencephaly examined and also in one of osteogenesis imperfecta. (2) Cortex: No lipoid was found in the cortical cells at 16 weeks. From 22 weeks onwards the cells of the middle zone show some vacuolation, and by 32 weeks a very intense Sudan III. staining is obtained in both the outer and the inner zone. This staining was also obtained in the cases of anencephaly and osteogenesis imperfecta mentioned above. In the few postnatal suprarenals which we had the opportunity of observing, the lipoid reaction of the cortex varied very considerably, but as no history as to cause of death was obtained the significance of this is not clear.

(*c*) *Physiological Test for Adrenin.*—The following tests for adrenin were most kindly carried out for us by Prof. F. Ransom. A 10 per cent. extract of the fresh whole gland was made in Ringer's solution, and its action tested on frogs: (*a*) On the peripheral circulation by perfusion; (*b*) on the heart beat by perfusion; (*c*) on the skin glands by subcutaneous injection; (*d*) on the enucleated eye by immersion. By this means the presence of a small but definite amount of adrenin was detected in the glands of fœtuses of 16 and 18 weeks maturity (younger glands have not as yet been tested), whereas the older glands contained a greater quantity. This bears out the observation of others that the presence of adrenin does not necessarily mean that a chromaphil reaction can be obtained in the cells.

Summary.

In conclusion, we wish it clearly to be understood that, although the dates mentioned are the earliest at which any appearance of function has been noted by us, it is quite possible that further investigation may show that these organs become active at yet earlier stages in the development of the fœtus.

1. The fœtal kidney begins to function at about the eleventh week of development. 2. The fœtal liver is functioning as an excretory organ at 12 weeks. 3. The fœtal gastric mucosa contains pepsin at 16 weeks, but no HCl even at full term. 4. The fœtal pancreas contains both trypsin and trypsinogen at 16 weeks; both are also present at full term. Pancreatic amylase is present at 24 weeks, and pancreatic lipase at 32 weeks. 5. Intestinal ferments are not present at 32 weeks, but enterokinase is present at 16 weeks; mucin is present at 8 weeks. 6. The fœtal pituitary contains an active principle at 8 weeks. 7. The fœtal thyroid is producing colloid-like secretion at 11 weeks. 8. The fœtal suprarenal contains adrenin at 16 weeks, but does not give a chromaphil reaction until very much later.

We offer our sincere thanks to all who have kindly supplied us with fœtal material. The expenses of this research have in part been met by a grant from the Thomas Smythe Hughes Medical Research Fund, and one of us (E. E. H.) has to thank the Medical Research Council for a part-time grant.

The infection had spread into the right kidney and the liver, producing in each of these organs a single large lesion consisting of multiple nodules, many of which had broken down in the centre and in some cases contained pus. Very few streptothrix granules were visible in these lesions. The mesenteric glands were somewhat enlarged and of a yellowish colour, but no granules were found in them. A number of small lesions, more numerous on the right side, were found scattered throughout both lungs; the majority of these were irregular in shape and firm in consistence, but a few contained pus. A small abscess containing actinomycotic granules was present in the spleen. No foci of infection were observable elsewhere in the body. The spleen was enlarged and showed advanced hyaline degeneration; a slighter degree of this form of degeneration was found in the kidneys, but none in the liver, which had undergone fatty degeneration. On microscopical examination sections of the lesions presented the usual appearance of granules embedded in a cellular zone with fibrous tissue at the periphery.

The Organism.

Granules for examination were obtained from the sinuses in the thoracic wall and from the sputum; post-mortem, sections of granules were seen in preparations made from the affected organs. Cultures were obtained from material discharged through the thoracic wall. The granules as seen in the pus and sputum consisted of masses of slender mycelial filaments, many of which were so short as to simulate bacilli. Branching was seen in a few instances. The filaments were Gram-positive and for the most part were evenly stained by this method, but a few threads were irregularly stained and presented a dotted appearance. No spores were seen in preparations from the pus. The presence of clubs was not demonstrated. The organism was not acid-fast. Granules from the pus were inoculated in broth and on the surface of glycerine agar and of Dorset's egg medium; stab cultures were prepared in glucose agar. In the primary cultures no growth of a streptothrix was obtained in the tubes incubated aerobically, all of which contained staphylococci; under anaerobic conditions the streptothrix grew in all the media inoculated, growth becoming visible about the fourth day. The organisms failed to thrive in subcultures. On the tenth day the surface colonies were greyish-white, heaped up, coherent; the majority were circular in outline. Fragmentation seems to have occurred in all the colonies; the appearance of the films was that of somewhat sinuous rod-segments with here and there a longer thread sometimes showing branching. In many individuals one end was swollen and contained a spore. Films prepared from the broth cultures presented similar appearances, and in an agar suspension culture examined as late as the seventeenth day no spores were found. Here the colonies were cream-coloured and irregular in shape.

The organism appears to show the main characteristics of the *Actinomyces bovis* as described by Wolff and Israel,[2] Homer Wright,[3] and Colebrook.[4] The filaments would seem to have been shorter than those usually described; this feature was particularly striking in preparations from the cultures. Israel and Wolff noticed a tendency for the organisms examined by them to assume a bacillary form on artificial media. Referring to the streptothrices in general Foulerton[5] draws attention to a tendency to the appearance of fragmentation and of spore formation on artificial media. It is not surprising, therefore, that these degenerate forms should be present in cultures examined as late as the tenth day.

We are indebted to Dr. F. G. Chandler and Dr. S. Roodhouse Gloyne for permission to publish the records of this case, and to Mr. A. W. Smart for preparing the sections for microscopical examination.

Clinical and Laboratory Notes.

THE PANCREAS OF TELEOSTEAN FISHES AND THE SOURCE OF INSULIN.

BY SWALE VINCENT, LL.D., D.SC., M.D.,
E. C. DODDS, M.B., B.S., B.SC.,
AND
F. DICKENS, B.A., PH.D.

(From the Physiological Department and the Biochemical Laboratory of the Bland-Sutton Institute, Middlesex Hospital Medical School.)

IT is well known that in teleostean fishes there is a more or less complete separation of the islets of Langerhans from the zymogenous tubules of the pancreas. This was pointed out years ago by Diamare, Rennie, and Vincent and Thompson.

Soon after the announcement by Banting, Best, Collip, and Macleod of the successful preparation of pancreatic extracts containing insulin, Macleod[1] turned his attention to the pancreas of teleosts in order to determine whether the active substance is in fact derived from the islets, or whether it may be obtained from zymogenous tissue and islet indiscriminately—that is to say, from the pancreas as a whole. He found that potent insulin preparations could be made from separated islet tissue of Lophius and Myoxocephalus. He failed to prepare any insulin from the pancreatic tissue proper (zymogenous or acinar) of Lophius, Myoxocephalus, or Zoarces. His conclusion was that insulin, as its name implies, is derived from the insular and not the zymogenous tissue of the pancreas.

At the outset it was suspected that the "islets" of the above-named species do not consist absolutely of islet tissue, but contain a certain amount of acinar material. It was also by no means certain that the somewhat elusive pancreas of teleosts was entirely free from islets. The degree of concentration of insular material into the "principal islets" varies within very wide limits. For this reason, and for the reason that considerable amounts of insulin were obtained[2] from, for example, submaxillary gland and other tissues, it was thought desirable to re-investigate the matter, using the method of Dodds and Dickens.[3] This method is particularly applicable to small quantities of material.

With this object we worked for a week in the laboratory of the Marine Biological Station at Plymouth. The two species investigated were *Lophius piscatorius* and *Myoxocephalus bubalis*. In the majority of specimens of both these species it is not difficult to obtain separately a fair amount of "principal islet" and of mesenteric zymogenous pancreas. Roughly speaking, the islet tissue has been found to yield six or seven times the amount of insulin obtainable from the same weight of zymogenous tissue. But it must be pointed out that our results differ from those obtained by Macleod in one important respect, for whereas he obtained no insulin whatever from zymogenous tissue we have found a very appreciable amount—enough, indeed, to produce definite symptoms of hypoglycæmia when tested upon rabbits in the usual way. This difference may probably be explained partly by the difference in the method of extraction, and partly by the precaution which we have taken to employ perfectly fresh material. With less fresh material, the amount of insulin obtained from zymogenous tissue was appreciably less. The main result of our investigation is, however, entirely confirmatory of that of Macleod.

It was found by Vincent and Thompson[4] in several lake and river teleosts that the "principal islet" was always permeated by strands of zymogenous tissue. Whether this is true in marine teleosts we cannot say until our histological material has

A CASE OF ACTINOMYCOSIS.

BY A. I. G. MCLAUGHLIN, M.B., CH.M. SYD.,
RESIDENT MEDICAL OFFICER, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK;

AND

D. S. PAGE, M.A., M.B. CAMB., D.P.H.,
ASSISTANT PATHOLOGIST TO THE HOSPITAL.

THE subject of this report was by occupation a tram-washer (previously a groom), aged 27, and was admitted to hospital on April 13th, 1923, complaining of a dull pain in the right side of the chest and a swelling over the ribs on the same side. The pain commenced three weeks before admission, and was severe and periodic in character for one week, after which it subsided to a persistent dull ache, and at the same time the swelling appeared on the right postero-lateral aspect of the chest, gradually increasing in size to about 5 inches long and 3 inches wide. There was slight cough and a trace of sputum.

Previous Health.—At the age of 5 he suffered from tuberculous caries of the spine and was treated by rest for 18 months. On Nov. 17th, 1922, he underwent an operation in the Hackney Infirmary for acute appendicitis. Dr. W. Brander, the medical superintendent, has kindly supplied the following information regarding the operation:—

> The patient was suffering from perforation of the appendix with general peritonitis. Our clinical notes state that the inflammation was limited to the terminal part of the appendix, which was perforated and sloughing at the tip. The peritoneal cavity was drained by a tube in the pelvis and by another in the renal gutter. There was no collection of pus, but a general peritonitis. The wounds had healed completely by Dec. 16th.

The patient attended the tuberculosis dispensary at this hospital on March 28th, 1923, and we are indebted to Dr. H. T. Howell and Dr. H. F. Hamilton for the following information:—

> He complained of a cough and sharp pains, aggravated by breathing, in the right side of the chest. Marked angular deformity of the spine in the upper thoracic region was observed. At the right base the percussion note was impaired, the breath sounds were feeble and were accompanied by sharp crepitations. No tubercle bacilli were found in the sputum, and the temperature was 98·8° F. He again attended the dispensary on April 13th, 1923, when a definite swelling, markedly tender, was found on the right postero-lateral aspect of the chest, extending from the inferior angle of the scapula to the tenth rib.

The patient was admitted to the hospital on the same day. On admission temperature was 99·8° F., pulse 120, and respirations 30. The patient was pale and rather wasted. There was some coarse clubbing of the fingers. The teeth were sound, the tongue clean, and the naso-pharynx normal. There was no tenderness or rigidity of the abdominal wall, and the liver and spleen were apparently normal in size.

The percussion note, vocal resonance, and fremitus were distinctly impaired over the base of the right lung, both anteriorly and posteriorly; no breath sounds were audible. Crepitations were detected over the left, but not over the right base. X ray examination showed diminished excursion of the right diaphragm and suggested the presence of a localised abscess at the right base. No lesion of the ribs was detected. There was evidence of old tuberculous caries of the fourth and fifth thoracic vertebræ, but none of active disease. The leucocyte count was 7700 per c.mm. Neither tubercle bacilli nor actinomyces were found in the sputum. The Wassermann reaction was negative.

On the day after admission it was found that the swelling had disappeared, but that there was still marked tenderness over the area. Two days later, however, the swelling reappeared, and during the next week became inflamed and the surrounding skin indurated, with some central fluctuation. On May 9th, 1923, it was incised, some pus containing greyish-white granules evacuated, and the cavity explored. No connexion with the pleural cavity could be found. A tube was inserted for 48 hours. The pathologist reported the presence of actinomyces in the pus. After the tube had been removed, there developed a persistent sinus discharging moderate quantities of pus containing the greyish-white granules. A larger area of the surrounding skin became inflamed and indurated, the subcutaneous induration occupying a wider area than that of the reddened skin, and after two weeks a second sinus had developed below and 2 inches to the left of the original sinus. A few weeks later a third and smaller sinus developed. As time went on the pus became less granular in appearance, but did not diminish in quantity.

In June, 1923, the general condition of the patient had improved considerably. The temperature was normal. there was no sputum, and the weight, which had gradually been decreasing, had become stationary. In July, however, he commenced to lose weight, and to have profuse night-sweats. The temperature became remittent and irregular. At first the morning temperature was higher than the evening reading, but after three weeks this was reversed. From this time the patient steadily became worse, the temperature more and more irregular, and the pulse more rapid. On Sept. 16th a rigor occurred lasting for ten minutes, and another two days later. There was no rise of temperature on either occasion. Actinomyces were found in the sputum for the first time on Oct. 5th. About this time he began to have slight diarrhœa, which gradually became more severe. In the fæces some filaments resembling mycelium were found, but the actinomyces was not definitely identified. The urine on many occasions was found to contain a large proportion of albumin, but there was unfortunately no special examination for actinomyces.

After the onset of severe diarrhœa the patient wasted rapidly, and the tongue and buccal mucous membrane became ulcerated. The ulcers were small, circumscribed, and shallow, and were situated mainly at the sides of the tongue and the corresponding buccal surfaces of the cheeks. The remaining mucous membrane of the tongue was red and glazed.

During the last ten days of the illness ascites and œdema of the feet and ankles supervened. Death occurred on Dec. 14th, after the patient had been under observation for eight months.

Treatment.

Surgical.—The abscess was incised, curetted, and drained, and the wound dressed with a solution of iodine one part, potassium iodide two parts, and water 300 parts. When the surrounding skin and subcutaneous tissue became reddened and indurated a dressing of ung. ichthyol (10 per cent.) was applied. This prevented the zone of inflammation from extending.

Medicinal.—From the outset gradually increasing doses of potassium iodide were given, until a maximum of 180 gr. per diem was reached, and this was continued for several months. With the exception of a period in June, when the patient's general condition had improved, there was no evidence that the administration of iodides had any marked beneficial effect. Later, gradually increasing doses of French tincture of iodine were given until a maximum of 120 minims per diem was reached.

Vaccine.—Subcutaneous injections of multivalent actinomyces vaccine with an initial dose of 1,000,000 mycelial fragments were commenced on Sept. 24th, and continued every five days, with an increase of 1,000,000 at each injection, until a maximum dose of 10,000,000 fragments was reached. Each injection was followed by a marked increase in the diarrhœa from which the patient was then suffering. No other reaction, either local or general, was observed.

The result of treatment, both with potassium iodide and with vaccines, seems to coincide more or less with the results obtained by Colebrook[1] in cases of thoracic and abdominal actinomycosis.

Autopsy.

The body showed a considerable degree of emaciation. Some œdema was present about the ankles. The sites of the abdominal operation wounds were indicated by the presence of healthy scar tissue. The viscera on the right side of the abdomen were bound together by adhesions; separation of the cæcum brought to view a small, greyish, necrotic area presumably corresponding with the site of the appendix amputation. Behind the peritoneum was a track of yellowish grey, somewhat purulent granulation tissue which, commencing behind the cæcum, passed upwards in front of the right kidney and behind the liver. Penetrating the diaphragm the organism had infected the lower part of the right pleura, which was separated from the healthy pleura by dense adhesions; the track of granulation tissue was continued into the thoracic wall and communicated with the exterior through a number of narrow sinuses.

The infection had spread into the right kidney and the liver, producing in each of these organs a single large lesion consisting of multiple nodules, many of which had broken down in the centre and in some cases contained pus. Very few streptothrix granules were visible in these lesions. The mesenteric glands were somewhat enlarged and of a yellowish colour, but no granules were found in them. A number of small lesions, more numerous on the right side, were found scattered throughout both lungs; the majority of these were irregular in shape and firm in consistence, but a few contained pus. A small abscess containing actinomycotic granules was present in the spleen. No foci of infection were observable elsewhere in the body. The spleen was enlarged and showed advanced hyaline degeneration; a slighter degree of this form of degeneration was found in the kidneys, but none in the liver, which had undergone fatty degeneration. On microscopical examination sections of the lesions presented the usual appearance of granules embedded in a cellular zone with fibrous tissue at the periphery.

The Organism.

Granules for examination were obtained from the sinuses in the thoracic wall and from the sputum; post-mortem, sections of granules were seen in preparations made from the affected organs. Cultures were obtained from material discharged through the thoracic wall. The granules as seen in the pus and sputum consisted of masses of slender mycelial filaments, many of which were so short as to simulate bacilli. Branching was seen in a few instances. The filaments were Gram-positive and for the most part were evenly stained by this method, but a few threads were irregularly stained and presented a dotted appearance. No spores were seen in preparations from the pus. The presence of clubs was not demonstrated. The organism was not acid-fast. Granules from the pus were inoculated in broth and on the surface of glycerine agar and of Dorset's egg medium; stab cultures were prepared in glucose agar. In the primary cultures no growth of a streptothrix was obtained in the tubes incubated aerobically, all of which contained staphylococci; under anaerobic conditions the streptothrix grew in all the media inoculated, growth becoming visible about the fourth day. The organisms failed to thrive in subcultures. On the tenth day the surface colonies were greyish-white, heaped up, coherent; the majority were circular in outline. Fragmentation seems to have occurred in all the colonies; the appearance of the films was that of somewhat sinuous rod-segments with here and there a longer thread sometimes showing branching. In many individuals one end was swollen and contained a spore. Films prepared from the broth cultures presented similar appearances, and in an agar suspension culture examined as late as the seventeenth day no spores were found. Here the colonies were cream-coloured and irregular in shape.

The organism appears to show the main characteristics of the *Actinomyces bovis* as described by Wolff and Israel,[2] Homer Wright,[3] and Colebrook.[4] The filaments would seem to have been shorter than those usually described; this feature was particularly striking in preparations from the cultures. Israel and Wolff noticed a tendency for the organisms examined by them to assume a bacillary form on artificial media. Referring to the streptothrices in general Foulerton[5] draws attention to a tendency to the appearance of fragmentation and of spore formation on artificial media. It is not surprising, therefore, that these degenerate forms should be present in cultures examined as late as the tenth day.

We are indebted to Dr. F. G. Chandler and Dr. S. Roodhouse Gloyne for permission to publish the records of this case, and to Mr. A. W. Smart for preparing the sections for microscopical examination.

Clinical and Laboratory Notes.

THE PANCREAS OF TELEOSTEAN FISHES AND THE SOURCE OF INSULIN.

BY SWALE VINCENT, LL.D., D.Sc., M.D.,
E. C. DODDS, M.B., B.S., B.Sc.,
AND
F. DICKENS, B.A., PH.D.

(*From the Physiological Department and the Biochemical Laboratory of the Bland-Sutton Institute, Middlesex Hospital Medical School.*)

IT is well known that in teleostean fishes there is a more or less complete separation of the islets of Langerhans from the zymogenous tubules of the pancreas. This was pointed out years ago by Diamare, Rennie, and Vincent and Thompson.

Soon after the announcement by Banting, Best, Collip, and Macleod of the successful preparation of pancreatic extracts containing insulin, Macleod[1] turned his attention to the pancreas of teleosts in order to determine whether the active substance is in fact derived from the islets, or whether it may be obtained from zymogenous tissue and islet indiscriminately—that is to say, from the pancreas as a whole. He found that potent insulin preparations could be made from separated islet tissue of Lophius and Myoxocephalus. He failed to prepare any insulin from the pancreatic tissue proper (zymogenous or acinar) of Lophius, Myoxocephalus, or Zoarces. His conclusion was that insulin, as its name implies, is derived from the insular and not the zymogenous tissue of the pancreas.

At the outset it was suspected that the "islets" of the above-named species do not consist absolutely of islet tissue, but contain a certain amount of acinar material. It was also by no means certain that the somewhat elusive pancreas of teleosts was entirely free from islets. The degree of concentration of insular material into the "principal islets" varies within very wide limits. For this reason, and for the reason that considerable amounts of insulin were obtained[2] from, for example, submaxillary gland and other tissues, it was thought desirable to re-investigate the matter, using the method of Dodds and Dickens.[3] This method is particularly applicable to small quantities of material.

With this object we worked for a week in the laboratory of the Marine Biological Station at Plymouth. The two species investigated were *Lophius piscatorius* and *Myoxocephalus bubalis*. In the majority of specimens of both these species it is not difficult to obtain separately a fair amount of "principal islet" and of mesenteric zymogenous pancreas. Roughly speaking, the islet tissue has been found to yield six or seven times the amount of insulin obtainable from the same weight of zymogenous tissue. But it must be pointed out that our results differ from those obtained by Macleod in one important respect, for whereas he obtained no insulin whatever from zymogenous tissue we have found a very appreciable amount—enough, indeed, to produce definite symptoms of hypoglycæmia when tested upon rabbits in the usual way. This difference may probably be explained partly by the difference in the method of extraction, and partly by the precaution which we have taken to employ perfectly fresh material. With less fresh material, the amount of insulin obtained from zymogenous tissue was appreciably less. The main result of our investigation is, however, entirely confirmatory of that of Macleod.

It was found by Vincent and Thompson[4] in several lake and river teleosts that the "principal islet" was always permeated by strands of zymogenous tissue. Whether this is true in marine teleosts we cannot say until our histological material has been examined, but it is certain that minute specks of islet tissue, visible to the naked eye, are scattered throughout the pyloric portion of the pancreas.

It must be confessed that, making due allowances for the possibility mentioned in the last paragraph, the result stands out very clearly that the source of insulin is, in fact, islet tissue. We are justified in assuming, at any rate provisionally, that this is true also in mammalian pancreas.

It appears then that, notwithstanding the intimate anatomical relationship between islet and zymogenous tubules, the numerous transition forms in all groups of vertebrates, and the transformation of alveolus into islet and vice versa under different physiological conditions, notwithstanding all these considerations, the temporary modification of tubule into islet carries with it the assumption of a new function, that of the internal secretion of insulin.

A full account, with details of this investigation, will appear at an early date.

INCIDENCE OF HEART LESIONS IN INFECTIVE ARTHRITIS.

BY T. WILSON FROGGATT, M.B., CH.B. SHEFF.,
HOUSE PHYSICIAN, DEVONSHIRE HOSPITAL, BUXTON.

IN view of the recent interest in various forms of rheumatism, and of the fact that most authors state that heart lesions are rare complications of rheumatoid, or infective, arthritis, the following figures may be of value :—

Fifty cases (all females) were taken in rotation as they were admitted to the Devonshire Hospital, all of the type known as chronic infective, or rheumatoid, arthritis, between 17 and 72 years of age, giving histories of onset between 12 and 55.

I have divided them into six groups according to the condition of the heart: (A) Cases showing a murmur at one or more valve areas, with dilatation and subjective symptoms of palpitation or dyspnœa. (B) Cases with dilatation and subjective symptoms but no murmur. (C) Cases with murmurs and enlargement, but showing no subjective symptoms. (D) Cases showing murmurs but no enlargement or symptoms traceable to the heart. (E) Cases showing cardiac irregularity but no other evidence of damage to the heart. (F) Cases showing no cardiac abnormality.

The relation of other factors in the history is shown in the table.

Group	A	B	C	D	E	F
Number of cases	5	2	2	10	1	30
Family history of chronic rheumatism	2	2	—	5	1	13
Family history of rheumatic fever	1	—	—	—	—	3
Existence of pyorrhœa	4	1	2	7	1	21
Disease of tonsils	1	1	—	3	—	4
No focus discovered	1	—	—	2	—	—
Personal history of rheumatic fever in childhood	1	—	—	1	—	—
History of "growing pains" in childhood	2	1	—	5	—	7
Average age of onset of infective arthritis	27·4	36·5	35·0	28·4	35·5	35·5
Average duration since onset, in years	16	6·5	2	7·4	3	7·6

The table shows, therefore, that there were heart lesions in 20 out of 50 cases admitted, only 2 of whom give a history of acute rheumatism which might account for it. The remainder were all healthy until the onset of their chronic arthritis, as far as one can discover.

The enormous incidence of pyorrhœa in these cases is worthy of note, in relation to any preventive campaign, as is also the large number of cases giving a history of arthritis in the family, which probably provided the infecting organisms in the first place.

I am indebted to the members of the honorary medical staff for permission to publish these figures.

A CASE OF TORSION OF THE OMENTUM SIMULATING APPENDIX ABSCESS.

BY MICHAEL W. BULMAN, M.S. LOND.,
F.R.C.S. ENG.,
ASSISTANT SURGEON, NORFOLK AND NORWICH HOSPITAL.

THE following case appears to be sufficiently uncommon to merit report :—

A. C., a married woman aged 44, was admitted to Salford Royal Hospital on Nov. 27th, 1923.

History.—For three days before admission the patient had suffered from pain in the right iliac fossa, which had commenced suddenly and had persisted up till the time of admission. She had vomited frequently. An enema given on the day before admission to hospital had had a large constipated result, but previous to this the bowels had not acted for a week. There were no urinary symptoms, menstruation was normal, and she had had no previous abdominal trouble. Since the birth of her last child she had noticed a prolapse of the uterus, and a hernia on the right side.

Condition on Examination.—Temperature 100° F., pulse 84. There was definite tenderness and rigidity in the right iliac fossa, and a tender mass could be felt extending inwards nearly to the middle line and upwards to the umbilicus. I could find no definite evidence of hernia. I detected nothing abnormal on rectal examination.

Operation.—A provisional diagnosis of appendix abscess was made and I opened the abdomen by a paramedian incision, displacing the right rectus muscle outwards. Lying in the region in which the lump had been felt was a somewhat rolled-up mass of purple, congested, almost gangrenous omentum. It consisted of approximately the right half of the great omentum, and its lower extremity disappeared behind the posterior surface of a previously undiagnosed, flaccid, unilocular ovarian cyst springing from the left ovary and occupying the cavity of the pelvis. Above, the congestion of the omentum ceased abruptly at a point about one inch below its attachment to the transverse colon. The left side of the omentum was normal, and there was a well-defined line of demarcation between it and the congested portion. Separation of the congested from the normal omentum and from the underlying small intestine was easily carried out by the finger tip, when a thin prolongation of the congested omentum was found, firmly adherent to the posterior surface of the ovarian cyst. This adhesion, which appeared to be of long standing, was divided. Except at its upper attachment the omentum was now free, and it could be seen that the congestion was due to a rotation of the right portion through half a circle to the left, round a broad base situated at the upper limit of the congested area. The diseased omentum was ligatured and removed. The appendix was thickened, bound down by adhesions, and chronically inflamed, but showed no sign of recent acute inflammation. Appendicectomy was performed. The ovarian cyst was also removed. It showed no sign of secondary change and there was no rotation of its pedicle. The abdomen was then closed. Convalescence was uneventful.

In referring to torsion of the great omentum text-books state that the condition is very uncommon and, when found, is usually associated with an irreducible right inguinal or femoral hernia. Thomson and Miles[1] state that, "in the absence of hernia torsion of the omentum has usually been mistaken for appendicitis or for an ovarian cyst, the pedicle of which has become twisted." I have no doubt that in this case the adhesion of the omentum to the ovarian cyst, by forming a lower point of attachment for the omentum, allowed of its rotation on its long axis with resulting strangulation.

I am indebted to Mr. Geoffrey Jefferson, assistant surgeon to the Salford Royal Hospital, for permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL MEETING OF THE SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY IN CONJUNCTION WITH THE AMERICAN PROCTOLOGIC SOCIETY.

THE annual clinical meeting of this subsection, in conjunction with the American Proctologic Society, was held on Wednesday, Thursday, and Friday, July 9th–11th, with Mr. Aslett Baldwin, the President, in the chair. The discussion on Wednesday on the

Treatment of Hæmorrhoids by Injection

was opened by Mr. H. Græme Anderson, who traced the history of this method. First employed by quacks, it was later taken up by American proctologists, and first introduced to this country by Mr. Swinford Edwards about 25 years ago. Many different substances had been employed, including solutions of carbolic acid, quinine and urea, perchloride of iron, &c. He then proceeded to describe his own technique; he employed a special needle and syringe and injected a 10 per cent. solution of carbolic acid containing glycerine. This method of treatment was applicable only to uncomplicated internal hæmorrhoids. About 15 per cent. of cases recurred, but could be relieved by a repetition of the operation.

Dr. C. E. Dukes discussed the pathological changes provoked by carbolic acid. By cutting a number of sections of hæmorrhoids, injected with carbolic acid and renewed at periods varying from 1 to 21 days he was able to follow the changes as they occurred. These were illustrated by microscope slides and epidiascope preparations. He arrived at the following conclusions: Carbolic acid caused an aseptic inflammation characterised by dilatation of the vessels, emigration of the leucocytes, and transudation of lymph. By this means the alien liquid was diluted and removed; thereafter the inflammation quickly subsided. Thrombosis was frequently found in the vessels of piles removed after periods longer than five days after injection. This was partly due to injury to vessels by the needle, and partly to damage to the vascular endothelium by carbolic acid. It was the secondary changes particularly in the intravascular clotting and subsequent fibrosis which had the beneficial effect upon the piles.

Mr. Swinford Edwards and Mr. J. P. Lockhart-Mummery and Dr. Alfred J. Zobel (San Francisco) continued the discussion. The last-named used the injection method in the case of patients who could not spare the time necessary for operation, since by the former method the patient was able to carry on his business whilst undergoing the treatment. He believed that a few were cured, but nearly all were relieved, and if recurrence took place patients were usually willing to submit themselves to further treatment.

Dr. Jack Halton (Florida) was an enthusiastic advocate of the injection method after personal experience of it. He believed that nine-tenths of uncomplicated cases were cured. He employed quinine urea 5 per cent. solution and injected 2 to 6 minims into each pile. Only one pile was treated at a time, and each pile might require three injections.

Mr. W. S. Perrin gave the results of treatment in 380 cases of uncomplicated piles by injection with 10 per cent. carbolic acid solution. About 50 per cent. were absolutely cured, and a little over 30 per cent. were substantially cured, but complained of trivial symptoms. Four cases of recurrence had needed re-injection and five had eventually to be operated upon. He had come to the conclusion that the method was applicable to most cases of uncomplicated piles provided they were not of very large size.

Mr. Cecil Rowntree considered that this method gave admirable results in those cases of uncomplicated hæmorrhoids in which hæmorrhage was the chief or only symptom.

Dr. F. L. Jelks (Memphis) opposed the injection treatment very strongly and described some disastrous cases which had come to him after being treated by injection.

Mr. Lionel E. C. Norbury had seen complicated fistulæ result from the injection of hæmorrhoids which were partly internal and partly external, and thought that this variety of hæmorrhoid should not be so treated.

Mr. Græme Anderson replied, and pointed out that bad results usually occurred from using too strong a solution. After trial of various solutions, he had adopted a 10 per cent. solution of carbolic acid as the best.

The discussion on Thursday, July 10th, was opened by Dr. Louis J. Hirschman (Detroit), who described his operation for

Prolapse of the Rectum,

which depended upon shortening the mesentery of the sigmoid through an abdominal incision. This was illustrated on the epidiascope. He claimed that the results of this operation were very satisfactory.

Mr. Lockhart-Mummery admitted the difficulty of treating this complaint and described his own operation.

Dr. William M. Beach (Pittsburg) pointed out that Dr. Hirschman's operation resembled that of Moscovitch.

Mr. W. E. Miles outlined the pathology of prolapse of the rectum and described a first, second, and third degree. The first and second degrees were easily treated by a variety of well-known operations, but the third degree (in which the peritoneum was included in the prolapse) was exceedingly difficult to treat, and he doubted whether Dr. Hirschman's operation would be successful in this stage.

Sir Charles Gordon-Watson said that prolapse of the rectum in children was curable by dieting and careful regulation of habits without any operation.

Dr. Ralph W. Jackson (Fall River) agreed that operation was rarely necessary for better-class children, but was imperative for the neglected children of the very poor classes. He then employed a cautery.

Pruritus Ani.

Dr. J. G. Montague exhibited a cinematograph film illustrating the pathology of this condition and its treatment by the operation he had devised. He considered that the irritation was due to the cutaneous nerve filaments being caught in masses of fibrous tissue which were formed, he believed, as a result of infection. The operation he performed resembled Ball's operation, except that he made four small incisions with blunt scissors. The operation was combined with treatment by vaccines of *B. coli* and *Staphylococcus albus*, which were the usual infecting organisms.

Sir Charles Gordon-Watson called attention to the enlarged anal papillæ often present in pruritus ani. A certain proportion of cases were cured by cauterisation of these papillæ.

Dr. Dukes gave the result of a histological study of the distribution of sensory nerves in enlarged anal papillæ. Contrary to the generally accepted statements he had been able to show that a plexus of nerves surrounded the blood-vessels and these terminated in tactile corpuscles. Microscopic slides were exhibited.

On Friday, July 11th, a discussion took place on the

Treatment of Carcinoma of the Rectum.

Mr. W. Ernest Miles, who opened, said that of the three methods of spread of cancer of the rectum, by direct extension, by the blood-stream, and by the lymphatic system, the last was of the greatest importance. He then dealt at considerable length with the lymphatic system of the rectum in its various divisions, intramural, intermediate, and external, and illustrated his remarks with diagrams and drawings of microscopic preparations. The intramural plexuses of fine lymphatics, he pointed out, did not have a very long course along the length of the bowel, but were partially separated into systems each occupying a short zone of bowel, and draining by larger trunks to glands lying outside the bowel. The most important of these was the ano-rectal group of 10 to 15 glands lying just above the levator ani. In all the specimens of cancer of the rectum he had examined these glands were infected by cancer cells, even when no other deposits were to be found. From the ano-rectal glands cancer might spread in three directions—upwards along the retro-rectal glands, laterally to the glands in the pelvis as far out as the obturator vessels, and downwards to the fat and glands in the ischio-rectal fossæ. From the retro-rectal glands the cancer cells might find their way to the paracolic glands higher up, so that the latter were not necessarily infected in series; it followed that one could not argue from the fact that the paracolic glands attached to a short section of excised bowel were free from cancerous deposit, that other glands higher in the paracolic chain were also free. Photographs of two specimens excised at operation were then shown. The first exhibited a secondary spread of the cancer upwards, laterally and downwards—widespread dissemination in spite of the fact that it was an early case. In the second the primary growth had extended around three-quarters of the circumference of the bowel. Microscopic examination showed that the cancer cells had already passed through the muscular coat of the bowel and lymphatics. Spread was taking place, though judged by clinical standards the growth was an early one, since it was freely movable. Fixation of a growth in the rectum indicated the passage of the cancer process through the fascia propria of the rectum and indicated a widespread dissemination and a grave prognostic outlook, even after a very radical operation. Mr. Miles maintained that the mesentery of the rectum and sigmoid in cancer of the rectum were comparable with the axillary contents in the case of cancer of the breast, and that it (the mesentery) should be removed as widely as possible in all cases, early or late, whether the contained glands were obviously infected or not. Nothing less was performed in breast cancer and nothing less should be performed in cancer of the rectum. The perineal operation failed in this important respect; he therefore practised and advocated the abdomino-perineal operation.

The Perineal Operation.

Mr. LOCKHART-MUMMERY said he performed the operation advocated by the previous speaker 20 years ago, but had abandoned it since 1913, except for the high cancers at the recto-sigmoidal junction. For cancer in the latter locality he recognised that it was the logical treatment and still performed it, but for other cancers of the rectum he had abandoned the abdomino-perineal operation in favour of the perineal one, which was attended with a lower mortality and applicable to a larger proportion of cases. There were many advantages in having a standardised operation in which the various technical details did not vary. He performed the perineal operation in two stages. The first was a colostomy, and the second, 14 days later, was the excision in one piece of the rectum and as much of the sigmoid and its mesentery as could be brought down together with the anus and surrounding skin, the contents of the ischio-rectal fossæ, and parts of the levatores ani. This operation removed all the glands primarily infected and some of those in the second group. He used spinal anæsthesia in conjunction with gas and oxygen for men, with "twilight sleep" for women. The patient was able to get up 14 days later and to go home within a month. The mortality of this operation taking all cases, private and hospital, together was 9·3 per cent. The recurrence figures were surprisingly low. During the years 1915–19 65 cases were submitted to this operation, of whom 30 were alive and well five years later. He thought that these figures were at least as good as those obtaining with the abdomino-perineal operation.

Dr. W. H. KIGER (Los Angeles) considered that Mr. Miles's operation was the best and most thorough that had yet been devised. He had been working on different lines and had had a considerable degree of success from the slow "cooking" of rectal cancers by low temperature heat. This method was based on the lower degree of resistance to heat of the cancer cell compared with the normal, and was advocated only for inoperable or for very early cases, when the patient refused an operation involving colostomy. He used electric cauteries introduced through a water-jacketed speculum. [These instruments were exhibited.] Although many of his cases appeared to be quite hopeless, he had six or eight patients alive and well five years after the destruction of a rectal cancer by slow cooking.

Advantages of Local Operations.

Mr. SWINFORD EDWARDS, while recognising the merits of the abdomino-perineal operation from a theoretical or pathological point of view, held that very good results could be obtained from a much less drastic procedure. He could recall three cases he had dealt with many years ago by local excision through a linear proctotomy with complete restoration of the bowel and a normal anus. He was uncertain of the fate of the third, but he knew that two were alive and well to-day. The perineal operation which he had largely practised (a modification of Kraske's) aimed at retaining the normal anus whenever possible—a very important matter from the patient's point of view. This operation, while obviously very incomplete from a pathological aspect, had given a cure-rate at three years of 45 per cent. in proven cancers, with a mortality of only 5 per cent. After seeing Mr. Miles's diagrams, he was convinced that he must almost invariably have left many secondary cancerous deposits in lymphatics. From this he could only conclude that these secondaries must in many cases wither up and become inert. He felt very strongly that when so great a degree of success attended these very limited operations, it was unjustifiable to submit patients to a procedure with a mortality of 20–30 per cent, even in expert hands, however perfect that operation might be from a pathological standpoint.

Dr. FRANK C. YEOMANS (New York) referred to the cancer campaign held in America with the object of getting earlier diagnosis of rectal and other cancers. A few ulcers of the rectum were of doubtful malignancy; in such cases he preferred the small risk of cutting out a portion for microscopy to the needless risk of submitting a patient with a benign ulcer to a cancer operation. A great improvement in the results of the more drastic cancer operations had recently set in owing to improvements in anæsthesia and operative technique. In New York the abdomino-perineal operation was standardised for cancers at the recto-sigmoidal junction, Balfour's operation for higher growths, and the perineal operation for lower ones. His own rule was to perform a perineal operation when the growth could be reached by the finger, and he had several cases alive and well seven or eight years after this operation.

Sir C. GORDON-WATSON agreed with Mr. Lockhart-Mummery. The abdomino-perineal operation, while undoubtedly superior on theoretical grounds, should be reserved for high growths, while for lower ones the perineal operation was the only one justifiable on clinical and practical grounds.

Dr. D. C. MCKENNEY (Buffalo) held a brief for the "glorified Whitehead" operation for those patients who refused any operation involving colostomy.

Mr. G. Grey Turner considered that Mr. Miles had evolved the theoretically perfect operation, but in his (Mr. Turner's) hands that operation was attended with a very high mortality. He then brought before the meeting the records of a number of cases treated by a sacral operation with a considerable degree of success. He had one case alive now 16 years after a sacral operation. Of 43 cases who had survived this operation, 12 could be claimed as cured and two had died of intercurrent disease. Even when not cured the patients often had great relief. As regards the question of retaining the normal anus, he felt that this could only be safely done in cases diagnosed very early. The occupations followed by some of his own cases showed that a properly made and regulated colostomy was not necessarily a serious inconvenience.

Dr. Curtice Rosser (Dallas) discussed the question of radiation of rectal cancers either by X rays or radium. In America Howard Kelly, of Baltimore, and Quirke, of New York, both claimed cures by radiation alone, and a higher cure-rate from the use of radiation combined with surgery than from surgery alone. While going through the records of his own cases he had come to the conclusion that growths originally benign frequently underwent malignant change.

A Statistical Survey.

Mr. W. B. Gabriel gave some statistical records from 130 cases operated on at St. Mark's Hospital by various surgeons. The operative mortality for all cases was 16 per cent. Sepsis accounted for the majority of deaths; four deaths occurred from urinary fistulæ, two from pneumonia, and one each from a variety of other causes, including post-operative obstruction due to a loop of small intestine being strangled in an opening in the peritoneum. 109 cases left the hospital, of whom 44 had since died; 80 per cent. of these deaths occurred within three years. Of the known sites of recurrence the pelvis and liver were the commonest. The oldest patient who still survived the perineal operation was now 82, and had been operated upon 13 years ago. The operability-rate had risen during the last five years from 44 per cent. to 54 per cent., due, perhaps, to more careful selection of the cases admitted to the wards. The percentage of cases alive and well, and showing no sign of recurrence, was 18 at three years after operation and 11·5 at five years.

Replies.

Mr. Miles, in reply, congratulated Mr. Lockhart-Mummery on the results he had obtained from the perineal operation. His own experience had been less fortunate. He had performed 59 perineal operations with one death and 56 recurrences. It was this experience which had led him to perform the abdomino-perineal operation, and to treat cancer in this situation as cancer elsewhere was treated by the removal of all the removable tissue which was likely to be infected. His mortality in 116 operations was 25 per cent., but of 53 cases operated upon since the war with improved anæsthesia (spinal anæsthesia combined with gas and oxygen) the mortality was 9·8 per cent. It was noticeable that ether had been administered in two cases since the war, and both these died. The operation he advocated demanded careful preparation, suitable anæsthesia, a well thought-out technique, and good after-treatment. In his hands it had yielded nearly 50 per cent. of cures.

Mr. Lockhart-Mummery thought that much depended upon the type of growth, and that what was chiefly lacking was some means of determining beforehand the degree of malignancy. He believed that some cases could not be cured by the most radical procedure, while others of apparently the same type might do admirably after a local excision.

The President remarked that he had performed the abdomino-perineal operation successfully upon a lady of over 76 years of age. She came back to see him when she was 85 years, accompanied by her husband, whom she had married since the operation.

JOINT MEETING OF THE SECTION OF ELECTRO-THERAPEUTICS OF THE ROYAL SOCIETY OF MEDICINE AND THE RONTGEN SOCIETY.

A joint meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine and the Rontgen Society was held on July 5th at the Radcliffe Infirmary, Oxford, when Sir Thomas Horder delivered the Mackenzie Davidson Memorial Lecture on the

Influence of Radiology on the Criteria of Disease.

He said that medicine was indebted to radiology even more than to pathology in the investigation of disease of the deep parts. The X rays furnished evidence on alteration in function as well as in structure. They indicated focal sepsis in regions where it could not be detected clinically, as, for example, in the tooth sockets and nasal sinuses. The lecturer spoke on the revelations of dental radiography and the discovery of pus in cases in which the dental surgeon could find no evidence of pyorrhœa. Even if no pus were present the X rays could reveal evidence of infection by the discovery of a thickened periodontal membrane. Sir Thomas Horder pointed out that the belief that if no pus were present there was no infection would lead to serious error. X rays had proved that nephroptosis was not the grave malady it was formerly supposed to be, and had shown that displacement of the kidney could exist without the symptoms which were originally thought to be due to faulty position. When symptoms were present treatment of the patient rather than of the kidney was required. It was by the X rays alone that it could be decided whether faulty position of the hollow viscera was maintained by lack of tone or by the presence of adhesions. The author emphasised the necessity of realising the variation in position of the hollow viscera which could occur in healthy individuals. This variation made it very difficult in some cases to decide what was normal and what was abnormal. Patients should always be examined in different postures and palpation should be made during radioscopic examination. With regard to the varying position, Sir Thomas Horder thought that efforts to ascertain standards might stultify conclusions drawn from radioscopic examination. X rays also showed the influence of psychic disturbance on the movements and position of the hollow viscera. Attention was called to a case under radioscopic examination in which the stomach dropped and its peristaltic movements ceased at the moment when the patient received a sudden unexpected blow. The discrepancies between clinical and radiographic findings in certain cases—e.g., the discovery of gastric succussion on the couch one day and the failure to discover gastric dilatation next day by X rays, showed the influence of the emotions on the alimentary canal. X rays showed that abdominal belts raised the viscera in cases of enteroptosis and that exercise caused a similar effect. X rays were, further, of great value in showing the presence of enlarged lymphatic glands in regions—e.g., the hila of the lungs—where they could not be detected clinically, and in showing the alterations in size which they could undergo. The rays also showed, in some cases of carcinoma of the breast, that the distribution of the growth was more extensive than that shown by clinical examination. They showed also that metastases in bone occurred much more frequently than was formerly thought. Patients were thought to be suffering from rheumatism whereas the rays showed the presence of secondary growths in bone, and good skiagrams showed rarefaction. With regard to the therapeutic uses of X rays in malignant growth, the lecturer said that X rays had altered our notions regarding the progressive character of malignant disease. Cancer was to some extent controllable by radiation, and many patients lived direct extension, by the blood-stream, and by the lymphatic system, the last was of the greatest importance. He then dealt at considerable length with the lymphatic system of the rectum in its various divisions, intramural, intermediate, and external, and illustrated his remarks with diagrams and drawings of microscopic preparations. The intramural plexuses of fine lymphatics, he pointed out, did not have a very long course along the length of the bowel, but were partially separated into systems each occupying a short zone of bowel, and draining by larger trunks to glands lying outside the bowel. The most important of these was the ano-rectal group of 10 to 15 glands lying just above the levator ani. In all the specimens of cancer of the rectum he had examined these glands were infected by cancer cells, even when no other deposits were to be found. From the ano-rectal glands cancer might spread in three directions—upwards along the retro-rectal glands, laterally to the glands in the pelvis as far out as the obturator vessels, and downwards to the fat and glands in the ischio-rectal fossæ. From the retro-rectal glands the cancer cells might find their way to the paracolic glands higher up, so that the latter were not necessarily infected in series; it followed that one could not argue from the fact that the paracolic glands attached to a short section of excised bowel were free from cancerous deposit, that other glands higher in the paracolic chain were also free. Photographs of two specimens excised at operation were then shown. The first exhibited a secondary spread of the cancer upwards, laterally and downwards—widespread dissemination in spite of the fact that it was an early case. In the second the primary growth had extended around three-quarters of the circumference of the bowel. Microscopic examination showed that the cancer cells had already passed through the muscular coat of the bowel and lymphatics. Spread was taking place, though judged by clinical standards the growth was an early one, since it was freely movable. Fixation of a growth in the rectum indicated the passage of the cancer process through the fascia propria of the rectum and indicated a widespread dissemination and a grave prognostic outlook, even after a very radical operation. Mr. Miles maintained that the mesentery of the rectum and sigmoid in cancer of the rectum were comparable with the axillary contents in the case of cancer of the breast, and that it (the mesentery) should be removed as widely as possible in all cases, early or late, whether the contained glands were obviously infected or not. Nothing less was performed in breast cancer and nothing less should be performed in cancer of the rectum. The perineal operation failed in this important respect; he therefore practised and advocated the abdomino-perineal operation.

The Perineal Operation.

Mr. Lockhart-Mummery said he performed the operation advocated by the previous speaker 20 years ago, but had abandoned it since 1913, except for the high cancers at the recto-sigmoidal junction. For cancer in the latter locality he recognised that it was the logical treatment and still performed it, but for other cancers of the rectum he had abandoned the abdomino-perineal operation in favour of the perineal one, which was attended with a lower mortality and applicable to a larger proportion of cases. There were many advantages in having a standardised operation in which the various technical details did not vary. He performed the perineal operation in two stages. The first was a colostomy, and the second, 14 days later, was the excision in one piece of the rectum and as much of the sigmoid and its mesentery as could be brought down together with the anus and surrounding skin, the contents of the ischio-rectal fossæ, and parts of the levatores ani. This operation removed all the glands primarily infected and some of those in the second group. He used spinal anæsthesia in conjunction with gas and oxygen for men, with "twilight sleep" for women. The patient was able to get up 14 days later and to go home within a month. The mortality of this operation taking all cases, private and hospital, together was 9·3 per cent. The recurrence figures were surprisingly low. During the years 1915–19 65 cases were submitted to this operation, of whom 30 were alive and well five years later. He thought that these figures were at least as good as those obtaining with the abdomino-perineal operation.

Dr. W. H. Kiger (Los Angeles) considered that Mr. Miles's operation was the best and most thorough that had yet been devised. He had been working on different lines and had had a considerable degree of success from the slow "cooking" of rectal cancers by low temperature heat. This method was based on the lower degree of resistance to heat of the cancer cell compared with the normal, and was advocated only for inoperable or for very early cases, when the patient refused an operation involving colostomy. He used electric cauteries introduced through a water-jacketed speculum. [These instruments were exhibited.] Although many of his cases appeared to be quite hopeless, he had six or eight patients alive and well five years after the destruction of a rectal cancer by slow cooking.

Advantages of Local Operations.

Mr. Swinford Edwards, while recognising the merits of the abdomino-perineal operation from a theoretical or pathological point of view, held that very good results could be obtained from a much less drastic procedure. He could recall three cases he had dealt with many years ago by local excision through a linear proctotomy with complete restoration of the bowel and a normal anus. He was uncertain of the fate of the third, but he knew that two were alive and well to-day. The perineal operation which he had largely practised (a modification of Kraske's) aimed at retaining the normal anus whenever possible—a very important matter from the patient's point of view. This operation, while obviously very incomplete from a pathological aspect, had given a cure-rate at three years of 45 per cent. in proven cancers, with a mortality of only 5 per cent. After seeing Mr. Miles's diagrams, he was convinced that he must almost invariably have left many secondary cancerous deposits in lymphatics. From this he could only conclude that these secondaries must in many cases wither up and become inert. He felt very strongly that when so great a degree of success attended these very limited operations, it was unjustifiable to submit patients to a procedure with a mortality of 20–30 per cent, even in expert hands, however perfect that operation might be from a pathological standpoint.

Dr. Frank C. Yeomans (New York) referred to the cancer campaign held in America with the object of getting earlier diagnosis of rectal and other cancers. A few ulcers of the rectum were of doubtful malignancy; in such cases he preferred the small risk of cutting out a portion for microscopy to the needless risk of submitting a patient with a benign ulcer to a cancer operation. A great improvement in the results of the more drastic cancer operations had recently set in owing to improvements in anæsthesia and operative technique. In New York the abdomino-perineal operation was standardised for cancers at the recto-sigmoidal junction. Balfour's operation for higher growths, and the perineal operation for lower ones. His own rule was to perform a perineal operation when the growth could be reached by the finger, and he had several cases alive and well seven or eight years after this operation.

Sir C. Gordon-Watson agreed with Mr. Lockhart-Mummery. The abdomino-perineal operation, while undoubtedly superior on theoretical grounds, should be reserved for high growths, while for lower ones the perineal operation was the only one justifiable on clinical and practical grounds.

Dr. D. C. McKenney (Buffalo) held a brief for the "glorified Whitehead" operation for those patients who refused any operation involving colostomy.

of the book largely depends upon the historical setting in which it is framed. We feel that we are the legitimate successors of Hippocrates and Celsus, of Paré and Lavater, and we gain a new conception of the continuity of our art and a new appreciation of the skill and insight of its founders. Every known variety of hernia receives full discussion, backed by ample statistical information and an elaborate bibliography.

The author shows sound judgment in the views and methods which he has selected for approval, and the value of the book is enhanced by an adequate description of those he would discard. Admirable illustrations are included.

UROLOGY.

Lehrbuch der Urologie. By Prof. Dr. HANS WILDBOLZ, Berne. Berlin: Julius Springer. 1924. Pp. 546. $8.60.

THIS is not only a text-book of urinary diseases, it includes also affections of the male organs of generation. Throughout we get the impression that the teaching is the outcome of personal experience and therefore the book becomes more valuable. It is not simply a compilation. Mostly the recommendations conform to English practice, but here and there appear notable differences. The author regards perineal prostatectomy as preferable to the suprapubic method. His own operation, in which he reconstitutes the prostatic urethra by suture, has a mortality of between 5 and 10 per cent. with fewer complications than the suprapubic method with a mortality of 10–15 per cent. The method given on p. 70 for estimating the size of the kidney pelvis is not very good or accurate. Pyelography can be made absolutely safe by taking proper precautions. For refractory pyelitis an in-dwelling ureteric catheter is recommended, a method of treatment scarcely ever adopted in this country. A hæmatogenous origin for perinephric abscess is still put forward, but the author rightly says that the rupture of a small cortical kidney abscess cannot be laid aside as the possible cause. The section on tuberculosis of the kidney is particularly good. The pitfalls and difficulties in diagnosis are clearly set forth. Like most continental surgeons the author lays a good deal of stress upon the indigo-carmine test and cryoscopy. Tumours of the testicle are rather inadequately treated.

Taken as a whole the work is a very good and satisfactory text-book. The most careful critic can only point to minor blemishes. The book is illustrated by a number of informative coloured and monotone plates which are beautifully reproduced.

HEARING.

By R. M. OGDEN, Professor of Education in Cornell University. London: Jonathan Cape. 1924. Pp. 351. 15s.

IN this book Prof. Ogden deals with the psychological aspect of hearing—that is, with the manner in which sound affects the conscious mind—and he travels through subjects many of which are of interest to medical men in general and to otologists in particular. In the first two chapters are described briefly, but adequately, the physics of the sound-wave and the anatomy of the hearing organ. This is followed by a disquisition on the physiological theories of hearing from that of Helmholtz to that of Wrightson; the author does not attempt to decide between the opposing "resonance" and "telephone" theories of audition.

Every variety of sound can be classified into the three groups of tones, vocables, and noises. A most interesting description of the attributes of tone is given, that of brightness is ascribed to variation of the wave-form whereby the pulsation is shortened in comparison to the wave-length so that the trough becomes longer than the crest. There is a long discussion of vocables, or the characteristics of vowel sounds, and of Hermann's theory of "formants"; but surely the sound of "ê," as in "fête," is not a pure vowel, but a diphthong. A large part of the book is concerned with the character of sounds in relation to music, and interesting references are included to the musical scales of primitive races, of ancient Greeks, and of Oriental peoples. A chapter of more direct medical interest deals with the localisation of sound. The physical conditions under which a binaural sound is localised are primarily three: (1) the intensity ratio of the sound at the two ears, (2) the phase-difference of the sound-wave, and (3) the relative time of arrival of the sound at the two ears. Interesting experiments are given as to the bearing of these three factors on localisation. A chapter on the pathology of hearing is rather disappointing; it is not sufficiently full to be of real value, and is perhaps a little out of place in a book of this kind. Of the experiment with a tuning fork on the vertex it is said: "If one of the external canals is closed, the intensity of the sound in the closed ear is increased by reason of the fact that the passage of the sound-waves outward is to some extent interfered with, so that the imprisoned column of air resonates"; but is this a satisfactory explanation? For it is certain that the same phenomenon occurs when the meatus is solidly filled with cerumen or any other material. The paragraphs on the nature of auditory defects, deaf-mutism, and mechanical aids to hearing are quite inadequate. The book ends with a criticism of musical education in America, and a plea for better aural education in speech, which would also be applicable to this country.

MINOR SURGERY AND BANDAGING.

Eighteenth edition. By GWYNNE WILLIAMS, F.R.C.S. London: J. and A. Churchill. 1924. Pp. 423. 10*s.* 6*d.*

A VOLUME which started upon its career in 1861 and which has passed through 18 editions may be regarded as something more than a classic, it is almost a household friend. It would be interesting to compare the last edition with the first and to see how much remains of the original pages, but it is certain, anyhow, that Christopher Heath would be the first to appreciate the sound common sense and the practical outlook of his grown-up child. In the preface the author expresses a modest hope that it may continue to be a guide to house-surgeons and students. There is scarcely a page from which the practising surgeon may not pick up a useful hint, from the tying of a knot to the putting up of a fractured femur. Incidentally, the chapters on fractures are particularly good and will repay careful study even by a surgeon of experience. We should like to recommend the book to those who teach surgery. Minor surgery is what the student should know thoroughly if he is to be efficient in any branch of his profession. He may leave hospital full of the latest details of gastrectomy and bone-grafting, but entirely unable to treat a dropped finger. A book like this would do much to restore in his teacher as well as in himself a true sense of proportion.

PHYSIOLOGY.

Human Physiology: A Practical Course. By C. G. DOUGLAS, C.M.G., M.C., D.M., F.R.S., Fellow of St. John's College, Oxford; and J. G. PRIESTLEY, M.C., D.M., Christopher Welch Lecturer in Clinical Physiology, University of Oxford. Oxford: Clarendon Press. 1924. Pp. 232. 12*s.* 6*d.*

FOR general utility as well as breadth, the course given for the Final Honour School of Physiology in Oxford must be admitted to come second to none. Local conditions are favourable, and such courses are not given elsewhere, for various reasons. Teachers who wish to imitate the Oxford course, which they may well desire to do, have now fairly full accounts of the wide range of exercises comprised in the studies at Oxford. The present book deserves nothing but praise—the description of experiments is admirably longer and more comfortably after their application. Sir Thomas Horder prophesied that these X rays would play a conspicuous part in the elucidation of the problems of malignant disease.

Prof. Sidney Russ read a paper entitled

Experimental Studies on the Lethal Doses of X Rays and Radium on Animal Tissues.

He defined a lethal dose as the dose which prevented proliferation of the malignant cells, not that which destroyed them. He described experiments which he had conducted on animals which were exposed to radiation after grafting malignant tissues in them. After exposure the growth was transplanted into another animal and its proliferative powers noted. After exposure for 40 minutes it was found that 60 per cent. of the growth proliferated. After exposure for 55 to 60 minutes 1 per cent. only proliferated. The latter now required a much longer time of exposure to prevent its proliferation. The part which proliferated required a still longer exposure. Even after the latter a portion proliferated and required an even longer exposure. A stage was eventually reached in which proliferation could not be prevented by an exposure which was not sufficient to kill the animal if given in toto.

Prof. Russ had conducted experiments which showed the relation between the doses of soft and hard rays which caused either epilation, blistering, or lethal effects.

	Epilation.	Blistering.	Lethal.
Soft rays	21	38	56
Hard rays.. ..	126	228	146

He showed that the product of the time of exposure to radium and the intensity of the irradiation gave no accurate idea of dosage. Even with very long exposures it is doubtful whether the deep-lying cells often receive a lethal dose. It had been shown that the dividing cells require a shorter exposure than the growing cell for lethal action, but there was no known method of making cells divide at an appreciably greater rate by artificial means.

This change of vulnerability to radiation, according to the phase of the life-cycle, was perhaps of some importance in radiotherapy, though there was no way by which the cells might artificially be brought into the dividing stage. Prof. Russ submitted that under ordinary conditions the lethal dose that is of importance is the lethal dose for the growing and not for the dividing cells.

Further experiments were described showing the effects which X rays and radium have upon the resistance of the host. Whereas large doses might lead to the death of an animal, it had been shown that repeated small doses spread over considerable periods increased the body-weight and prevented such vigorous growth of tumour transplantations as occurs in the normal rat. Prof. Russ suggested that it might be well to supplement the thorough localised irradiation of a tumour by small generalised doses of radiation designed to increase the resistance to human growth.

Manchester and Maternity Nursing.—A new maternity home for 18 beds is about to be opened in Victoria Park by the Manchester and Salford District Nursing Institution, the intention being to make this a hospital for those who are prepared to pay from three and a half to five guineas a week for accommodation and skilled nursing. In addition, the home will also be a midwifery training centre for pupil midwives, and will assist institution nurses who wish to qualify for the C.M.B. certificate. Dr. Frances Ivens, of Liverpool, said that maternal mortality had not lessened in the last 20 years. To bear a child should be a normal physiological process, but it was often fatal and was often followed by terrible morbidity. The infant mortality-rate had been halved, and they must do the same with the maternal mortality-rate. The annual report showed that 57 nurses had been employed during the year and paid 164,101 visits. Over 8000 new patients had been attended, and the patients themselves had contributed £2046 to the funds.

Reviews and Notices of Books.

Practice of Medicine.

An Introduction to the Practice of Medicine. By William Boxwell, M.D. Dub., F.R.C.P.I., Professor of Pathology, Royal College of Surgeons, Ireland; Physician to the Meath Hospital, Dublin; and F. C. Purser, M.D. Dub., F.R.C.P.I., Professor of Medicine, Royal College of Surgeons, Ireland; Physician to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin. London: Baillière, Tindall and Cox. Dublin: The Talbot Press, Ltd. 1924. Pp. 905.

Considerable courage is required to produce a new text-book for the use of medical students during their first years of clinical study. Established text-books have proved their worth, but, whilst their steady increase in size is a tribute to the progress of medicine, it has certainly rendered them dangerously bulky for the beginner.

The writers have approached their task from a new aspect. A brief account of general pathological and physiological features is introduced before the description of each disease or group of diseases, and it seems certain that this method is one calculated to be useful to the student, whose entry to the wards lies through the laboratories. We feel that high praise is due to the authors for the boldness of their endeavour and, if in some details we disagree, the general scope of their work must remain unchallenged. The section devoted to diseases of the nervous system appears disproportionately long; thus the account of asphasia on p. 756 contains such detailed description of the history of Broca's discoveries that the subsequent exposition of Marie's views is overshadowed, while if phenomena such as apraxia require exposition a fuller description of them seems desirable. On the other hand, the description of the significance of Babinski's signs is better than is usually given and the importance of these signs is well emphasised. The account of encephalitis lethargica on p. 628 will appear inadequate to readers in this country. In the section dealing with diseases of the ductless glands, the authors include diabetes mellitus, a classification justified by recent advances; the biochemical pathology here described is clearly written, but the statement on p. 807 that an estimation of blood-sugar should be made before and after the administration of every dose of insulin is one calculated to alarm both practitioner and patient and to bring disrepute upon an invaluable remedy. Future editions should receive drastic revision of the sections devoted to chemical laboratory tests. The present account of the tests for pancreatic insufficiency lays no stress on the importance of examining the fæces; Fehling's solution rather than Benedict's is recommended, and Rothera's test for acetone is not given; nor is mention made of the value of estimating the urea and non-protein nitrogen in the blood.

The general conception of this book is excellent; it keeps the pathological aspects of medicine clearly before the minds of its readers.

Hernia.

Its Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis, and Operative Treatment. By Leigh F. Watson, M.D., Associate in Surgery, Rush Medical College, Chicago, U.S.A. London: Henry Kimpton. 1924. Pp. 660. *52s. 6d.*

The author has accomplished his aim at producing a complete treatise on hernia. He has written a large but eminently readable volume, packed with information. Whether he is tracing the history of hernia from ancient Egypt through Greece and Rome, or discussing the latest applications of local anæsthesia, he equally succeeds in infecting the reader with his own enthusiasm for his subject. The attraction of the book largely depends upon the historical setting in which it is framed. We feel that we are the legitimate successors of Hippocrates and Celsus, of Paré and Lavater, and we gain a new conception of the continuity of our art and a new appreciation of the skill and insight of its founders. Every known variety of hernia receives full discussion, backed by ample statistical information and an elaborate bibliography.

The author shows sound judgment in the views and methods which he has selected for approval, and the value of the book is enhanced by an adequate description of those he would discard. Admirable illustrations are included.

UROLOGY.

Lehrbuch der Urologie. By Prof. Dr. HANS WILDBOLZ, Berne. Berlin: Julius Springer. 1924. Pp. 546. $8.60.

THIS is not only a text-book of urinary diseases, it includes also affections of the male organs of generation. Throughout we get the impression that the teaching is the outcome of personal experience and therefore the book becomes more valuable. It is not simply a compilation. Mostly the recommendations conform to English practice, but here and there appear notable differences. The author regards perineal prostatectomy as preferable to the suprapubic method. His own operation, in which he reconstitutes the prostatic urethra by suture, has a mortality of between 5 and 10 per cent. with fewer complications than the suprapubic method with a mortality of 10–15 per cent. The method given on p. 70 for estimating the size of the kidney pelvis is not very good or accurate. Pyelography can be made absolutely safe by taking proper precautions. For refractory pyelitis an in-dwelling ureteric catheter is recommended, a method of treatment scarcely ever adopted in this country. A hæmatogenous origin for perinephric abscess is still put forward, but the author rightly says that the rupture of a small cortical kidney abscess cannot be laid aside as the possible cause. The section on tuberculosis of the kidney is particularly good. The pitfalls and difficulties in diagnosis are clearly set forth. Like most continental surgeons the author lays a good deal of stress upon the indigo-carmine test and cryoscopy. Tumours of the testicle are rather inadequately treated.

Taken as a whole the work is a very good and satisfactory text-book. The most careful critic can only point to minor blemishes. The book is illustrated by a number of informative coloured and monotone plates which are beautifully reproduced.

HEARING.

By R. M. OGDEN, Professor of Education in Cornell University. London: Jonathan Cape. 1924. Pp. 351. 15s.

IN this book Prof. Ogden deals with the psychological aspect of hearing—that is, with the manner in which sound affects the conscious mind—and he travels through subjects many of which are of interest to medical men in general and to otologists in particular. In the first two chapters are described briefly, but adequately, the physics of the sound-wave and the anatomy of the hearing organ. This is followed by a disquisition on the physiological theories of hearing from that of Helmholtz to that of Wrightson; the author does not attempt to decide between the opposing "resonance" and "telephone" theories of audition.

Every variety of sound can be classified into the three groups of tones, vocables, and noises. A most interesting description of the attributes of tone is given, that of brightness is ascribed to variation of the wave-form whereby the pulsation is shortened in comparison to the wave-length so that the [illegible] becomes longer than the crest. There is a long discussion of vocables, or the characteristics of vowel sounds, and of Hermann's theory of "formants"; but surely the sound of "ê," as in "fête," is not a pure vowel, but a diphthong. A large part of the book is concerned with the character of sounds in relation to music, and interesting references are included to the musical scales of primitive races, of ancient Greeks, and of Oriental peoples. A chapter of more direct medical interest deals with the localisation of sound. The physical conditions under which a binaural sound is localised are primarily three: (1) the intensity ratio of the sound at the two ears, (2) the phase-difference of the sound-wave, and (3) the relative time of arrival of the sound at the two ears. Interesting experiments are given as to the bearing of these three factors on localisation. A chapter on the pathology of hearing is rather disappointing; it is not sufficiently full to be of real value, and is perhaps a little out of place in a book of this kind. Of the experiment with a tuning fork on the vertex it is said: "If one of the external canals is closed, the intensity of the sound in the closed ear is increased by reason of the fact that the passage of the sound-waves outward is to some extent interfered with, so that the imprisoned column of air resonates"; but is this a satisfactory explanation? For it is certain that the same phenomenon occurs when the meatus is solidly filled with cerumen or any other material. The paragraphs on the nature of auditory defects, deaf-mutism, and mechanical aids to hearing are quite inadequate. The book ends with a criticism of musical education in America, and a plea for better aural education in speech, which would also be applicable to this country.

MINOR SURGERY AND BANDAGING.

Eighteenth edition. By GWYNNE WILLIAMS, F.R.C.S. London: J. and A. Churchill. 1924. Pp. 423. 10s. 6d.

A VOLUME which started upon its career in 1861 and which has passed through 18 editions may be regarded as something more than a classic; it is almost a household friend. It would be interesting to compare the last edition with the first and to see how much remains of the original pages, but it is certain, anyhow, that Christopher Heath would be the first to appreciate the sound common sense and the practical outlook of his grown-up child. In the preface the author expresses a modest hope that it may continue to be a guide to house-surgeons and students. There is scarcely a page from which the practising surgeon may not pick up a useful hint, from the tying of a knot to the putting up of a fractured femur. Incidentally, the chapters on fractures are particularly good and will repay careful study even by a surgeon of experience. We should like to recommend the book to those who teach surgery. Minor surgery is what the student should know thoroughly if he is to be efficient in any branch of his profession. He may leave hospital full of the latest details of gastrectomy and bone-grafting, but entirely unable to treat a crushed finger. A book like this would do much to restore in the teacher as well as in himself a sense of proportion.

PHYSIOLOGY.

Human Physiology: A Practical Course. By C. G. DOUGLAS, C.M.G., M.C., D.M., [illegible] Fellow of St. John's College, Oxford, and J. G. PRIESTLEY, M.C., B.M., B.Ch., [illegible] in Clinical Physiology, University of [illegible] Oxford: Clarendon Press. 1924. [illegible]

FOR general utility as well as [illegible] given for the final Honour School [illegible] Oxford and the admitted [illegible] local conditions [illegible] who wish to imitate [illegible] may well [illegible] at Oxford. The [illegible] practice. The [illegible] longer and more comfortably after their application. Sir Thomas Horder prophesied that these X rays would play a conspicuous part in the elucidation of the problems of malignant disease.

Prof. SIDNEY RUSS read a paper entitled

Experimental Studies on the Lethal Doses of X Rays and Radium on Animal Tissues.

He defined a lethal dose as the dose which prevented proliferation of the malignant cells, not that which destroyed them. He described experiments which he had conducted on animals which were exposed to radiation after grafting malignant tissues in them. After exposure the growth was transplanted into another animal and its proliferative powers noted. After exposure for 40 minutes it was found that 60 per cent. of the growth proliferated. After exposure for 55 to 60 minutes 1 per cent. only proliferated. The latter now required a much longer time of exposure to prevent its proliferation. The part which proliferated required a still longer exposure. Even after the latter a portion proliferated and required an even longer exposure. A stage was eventually reached in which proliferation could not be prevented by an exposure which was not sufficient to kill the animal if given in toto.

Prof. Russ had conducted experiments which showed the relation between the doses of soft and hard rays which caused either epilation, blistering, or lethal effects.

	Epilation.	Blistering.	Lethal.
Soft rays	21	38	56
Hard rays.. ..	126	228	146

He showed that the product of the time of exposure to radium and the intensity of the irradiation gave no accurate idea of dosage. Even with very long exposures it is doubtful whether the deep-lying cells often receive a lethal dose. It had been shown that the dividing cells require a shorter exposure than the growing cell for lethal action, but there was no known method of making cells divide at an appreciably greater rate by artificial means.

This change of vulnerability to radiation, according to the phase of the life-cycle, was perhaps of some importance in radiotherapy, though there was no way by which the cells might artificially be brought into the dividing stage. Prof. Russ submitted that under ordinary conditions the lethal dose that is of importance is the lethal dose for the growing and not for the dividing cells.

Further experiments were described showing the effects which X rays and radium have upon the resistance of the host. Whereas large doses might lead to the death of an animal, it had been shown that repeated small doses spread over considerable periods increased the body-weight and prevented such vigorous growth of tumour transplantations as occurs in the normal rat. Prof. Russ suggested that it might be well to supplement the thorough localised irradiation of a tumour by small generalised doses of radiation designed to increase the resistance to human growth.

MANCHESTER AND MATERNITY NURSING.—A new maternity home for 18 beds is about to be opened in Victoria Park by the Manchester and Salford District Nursing Institution, the intention being to make this a hospital for those who are prepared to pay from three and a half to five guineas a week for accommodation and skilled nursing. In addition, the home will also be a midwifery training centre for pupil midwives, and will assist institution nurses who wish to qualify for the C.M.B. certificate. Dr. Frances Ivens, of Liverpool, said that maternal mortality had not lessened in the last 20 years. To bear a child should be a normal physiological process, but it was often fatal and was often followed by terrible morbidity. The infant mortality-rate had been halved, and they must do the same with the maternal mortality-rate. The annual report showed that 57 nurses had been employed during the year and paid 164,101 visits. Over 8000 new patients had been attended, and the patients themselves had contributed £2046 to the funds.

PRACTICE OF MEDICINE.

An Introduction to the Practice of Medicine. By WILLIAM BOXWELL, M.D. Dub., F.R.C.P.I., Professor of Pathology, Royal College of Surgeons, Ireland; Physician to the Meath Hospital, Dublin; and F. C. PURSER, M.D. Dub., F.R.C.P.I., Professor of Medicine, Royal College of Surgeons, Ireland; Physician to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin. London: Baillière, Tindall and Cox. Dublin: The Talbot Press, Ltd. 1924. Pp. 905.

CONSIDERABLE courage is required to produce a new text-book for the use of medical students during their first years of clinical study. Established text-books have proved their worth, but, whilst their steady increase in size is a tribute to the progress of medicine, it has certainly rendered them dangerously bulky for the beginner.

The writers have approached their task from a new aspect. A brief account of general pathological and physiological features is introduced before the description of each disease or group of diseases, and it seems certain that this method is one calculated to be useful to the student, whose entry to the wards lies through the laboratories. We feel that high praise is due to the authors for the boldness of their endeavour and, if in some details we disagree, the general scope of their work must remain unchallenged. The section devoted to diseases of the nervous system appears disproportionately long; thus the account of asphasia on p. 756 contains such detailed description of the history of Broca's discoveries that the subsequent exposition of Marie's views is overshadowed, while if phenomena such as apraxia require exposition a fuller description of them seems desirable. On the other hand, the description of the significance of Babinski's signs is better than is usually given and the importance of these signs is well emphasised. The account of encephalitis lethargica on p. 628 will appear inadequate to readers in this country. In the section dealing with diseases of the ductless glands, the authors include diabetes mellitus, a classification justified by recent advances; the biochemical pathology here described is clearly written, but the statement on p. 807 that an estimation of blood-sugar should be made before and after the administration of every dose of insulin is one calculated to alarm both practitioner and patient and to bring disrepute upon an invaluable remedy. Future editions should receive drastic revision of the sections devoted to chemical laboratory tests. The present account of the tests for pancreatic insufficiency lays no stress on the importance of examining the fæces; Fehling's solution rather than Benedict's is recommended, and Rothera's test for acetone is not given; nor is mention made of the value of estimating the urea and non-protein nitrogen in the blood.

The general conception of this book is excellent; it keeps the pathological aspects of medicine clearly before the minds of its readers.

HERNIA.

Its Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis, and Operative Treatment. By LEIGH F. WATSON, M.D., Associate in Surgery, Rush Medical College, Chicago, U.S.A. London: Henry Kimpton. 1924. Pp. 660. *52s. 6d.*

THE author has accomplished his aim at producing a complete treatise on hernia. He has written a large but eminently readable volume, packed with information. Whether he is tracing the history of hernia from ancient Egypt through Greece and Rome, or discussing the latest applications of local anæsthesia, he equally succeeds in infecting the reader with his own enthusiasm for his subject. The attraction

DILETTANTISM IN RADIOLOGY.

THE indictment against dilettantism in radiology, brought by Dr. AXEL REYN, which was endorsed by other speakers at a recent meeting in Copenhagen of the Danish Medical Society, sets out a difficult and extensive problem. "Who is to decide," said Dr. REYN, "between the dilettante and the skilled radiologist"?—and the following are the two questions that would seem to call for consideration under his general inquiry: Is there, in the present position of radiological science, a place for any but the skilled and trained radiologist? And if so, by what criteria shall the necessary distinction be made?

Probably no discovery in physics has ever created so widespread a commotion or evolved more immediate interest than that of Prof. ROENTGEN in 1895, the obvious reason being that the superficial results were so striking and so easily appreciated. From the earliest days following the discovery, with very inadequate apparatus, with little or no knowledge of the physics of the subject, and with no literature to guide them, scientific men, both lay and medical, began to experiment with the new rays. Many of these men fell victims to their own enthusiasm, and to a heroic spirit which kept them still pursuing when the dangers had become apparent while no safeguards had arrived. This early band of workers included the dilettanti of their time, and let us recollect that we owe to these pioneers the foundation of the science and practice of radiology. Of the earlier workers many, fortunately, are still with us, while the scientific aspects of radiology have been put on a sound basis and a mass of tested knowledge has come into existence. The first dilettanti have developed, many of them, into our leaders, and for them the foreign word possesses no disparaging meaning. But they are not the semi-amateurs to whom the speakers at the Danish Conference were referring, who divide themselves roughly into several classes between which discrimination has to be exercised. There is the man who, in the first instance, has taken up X ray work as a hobby, and who passes into specialism without adequate training and, to a great extent, without knowing what he lacks. He is not to be confused with the man who believes that he can purchase an apparatus of such simplicity that it is fool-proof, but he none the less, and however unconsciously, represents badly the section of science which he essays to work at. There is also a most difficult class of radiologists to estimate in terms of professional utility. It is composed of physicians or surgeons who may be really wise and progressive, and who think that the interest of their patients may be served by their becoming their own radiologists. We need say nothing further of him who trusts to an instrument he does not understand. So quick will be the disillusionment that his class must always be a small one—the only fear is that its size should be magnified in popular opinion. Those who began by indulging a hobby will include both medical and non-medical persons, their existence may well be a danger, unless they are acting in a subordinate capacity and under very definite supervision. The consultant by doing all his own spade-work may lose something of his fineness of judgment and imitate the judge who plays the advocate. We know that there are exceptions to this generalisation, but any hasty or not absolutely necessary action by this group may give a very serious set-back to the growth of "team-work" in this country. This would be a calamity.

In the case of X ray therapy there is, we feel, nothing that can be said in favour of practice being in the hands of other than skilled and experienced men. If the present tendency towards the employment of more intensive therapy continues, the problems to be solved will be of magnitude. Even now it is impossible to exaggerate the necessity for careful selection of cases suitable for radiotherapy, and for the most precise indications as to dosage and definite skilled supervision during treatment. All these things imply not only special knowledge but experience, and they constitute the considerations which led to the institution of a special diploma in radiology. The interests of the patient above all, the difficulty of X ray diagnosis, and the great handicaps experienced by the early workers, were all factors in the minds of those who urged the advisability of special training. The University of Cambridge took up the matter with enthusiasm and laid down a course with a minimum of six months training, followed by an examination of sufficiently searching a nature to exclude the dilettante. The University insists upon a good grounding in the physics of radiography. No diploma of whatever nature can be regarded as more than a certificate implying that a candidate has learnt the elements of the subject, and for no other reason are they to be commended. The holder of a diploma in radiology is in a much better position to acquire experience than the man without it—that is the point to be remembered.

RATIONS FOR EXPERIMENTAL AND DOMESTIC ANIMALS.

AT first sight it seems an easy task to construct a dietary for animals on which they can be maintained in good health over an indefinite period of time—a maintenance diet as Prof. R. G. LINTON calls it in the special article which we publish to-day. The problem is one which is of considerable importance to breeders of animals. It also is of interest to those who have to maintain large numbers of animals in field laboratories for experimental purposes. Since economic conditions enforce dietetic restrictions on man, the problem has also an important bearing on human dietetics. It is implied in the problem that the diet must be an economical one, and one which can be readily administered. The choice of foodstuffs is therefore limited and variations in the dietary are excluded. It is this absence of variety which introduces the difficulty, for almost any one of the common foodstuffs, except milk, will result, if given alone over a long enough period, in a deficiency of either specific amino acids or of certain inorganic elements or vitamins. Such a deficiency may not be so severe as to produce obvious ill-health or disease, and may only reveal itself if the animals are kept over very long periods of time by a diminished fertility, by increased susceptibility to infections, or by slight pathological changes which are only found post-mortem when looked for, such as the bone changes discovered in monkeys kept in the Zoo. At present our knowledge on these points is very imperfect because most experiments on dietetics have been carried out only over very short periods of time.

clear and the selection of experiments is carefully made. The book naturally deals in adequate detail with those observations on respiration and on the blood-gases for which the school is famous, and it is satisfactory to have a connected record of the methods used. There are also chapters on the use of instruments for the investigation of the circulation, and on the secretion of urine and the movements of the alimentary canal. A few chemical methods, such as some of the important ones for determination of blood-sugar and urea, are included. To teachers and advanced students the book will be very useful, and it is regrettable that the equipment and technique involved preclude the carrying out of such exercises by the ordinary medical student. To the clinical research worker the book may, we think, show itself indispensable.

Collected Papers, Institute of Physiology, University College, London. Vol. XXI. Edited by ERNEST H. STARLING, C.M.G., M.D., Sc.D., F.R.S., Sir WM. M. BAYLISS, M.A., Sc.D., F.R.S., and J. C. DRUMMOND, D.Sc., F.I.C. 1923.

THE 45 papers which comprise this closing volume of a remarkable series, show the same high standard of excellence which has marked all the volumes of collected papers published during the time that Prof. Starling was the head of the University College Institute of Physiology. The papers fall roughly into three groups, corresponding to the direction of inquiry followed by each of the three professors who edit the collection. About half of the papers represent work on vitamins by Prof. Drummond and various collaborators, particularly Miss Katharine Coward and Dr. S. S. Zilva; these papers have contributed largely towards giving the Biochemical Department of this College a high status. Original work breaking some fresh ground is that by Drs. G. V. Anrep and R. K. Cannan on the metabolism of the salivary glands, and on the effect of alteration of blood reaction on the lactic acid concentration of the blood. An interesting paper on active hyperæmia is contributed by Dr. D. T. Harris. Prof. Starling and various collaborators contribute papers on the heart, and Sir William Bayliss, as usual, ranges over a wide field of subjects. This volume contains two of his papers on the effects of hæmorrhage.

Questions Actuelles de Biologie Médicale. By G. H. ROGER, Doyen de la Faculté de Médecine de Paris; Professeur de Pathologie Expérimentale et Comparée; Membre de l'Académie de Médecine. Paris: Masson et Cie. 1924. Pp. 194. Fr.16.

THE seven essays contained in this book represent the conclusions of some of the author's researches, part of which have been already published as separate papers. Among the subjects treated are the lipolytic and detoxifying action of the lungs, various effects of injection of autolytic products of the lungs and of other animal extracts, the functions of the suprarenals especially with regard to their relation to the hypertension of cerebral embolism, the action of the liver on toxic substances, various researches on enzymes, and a chapter on the functions of the bile. This last is one of the most interesting in the book; one of the hypotheses advanced is that the bile counteracts an enzyme mucino-coagulase, and so inhibits the coagulation of mucin. In muco-membranous colitis, for one reason or another, coagulation of mucus occurs. As a whole the book provides highly entertaining reading, and one leaves it with a feeling of admiration for the author's ingenuity.

DIET FOR CHILDREN.
By CECIL WEBB-JOHNSON, M.B., Ch.B., Major R.A.M.C. (T.F.), late Civil Surgeon and O.C. Station Hospital, Dum-Dum. London: Mills and Boon. 1924. Pp. 128. 3*s.* 6*d.*

IT is not necessary to agree with their contents in entirety to find that Dr. Cecil Webb-Johnson's various works on diet contain much good common sense, so that their appeal to the lay reader, for whom they are intended, is justified. This is in many ways the best of his books; it shows a balance and a tolerance of opinions current among authorities on the scientific side of diet which have not always marked his previous works. He is still averse, though not so bitterly, to the use of milk. Though it would be easy to find fault with the scientific aspects of the book, it is one which is capable of being understood by those with no knowledge of science, and is likely to do much more good than harm.

New Inventions.

SPECIAL BOX FOR THE RADIANT HEAT TREATMENT OF INFECTED FINGERS AND HANDS.

THE use of radiant heat in treatment of infected fingers and hands has been mentioned by several authors,[1] and Messrs. John Weiss and Son have made a special box to my design for the hot-air treatment of such cases. The box is made of wood and is lined with asbestos and measures 13 in. by 10 in. by 7 in. Four long cylindrical carbon filament lamps give the heat and they can be supplied at the desired voltage. They are shaded by strips of asbestos to prevent any possibility of the lamp touching and so burning the hand. A thermometer has been fixed into the top of the box, so that the reading may easily be checked. The illustration shows the arrangement, the two halves of the box being equal in size, and the whole apparatus is light and easy to use. The hand is placed in the box, which is then shut and securely fastened, and any gaps left around the wrist at the entrance to the box are closed with wool or a towel. The current is switched on and the temperature allowed to reach 120° F.—which it does in five minutes—and it is then kept at that level for 20 minutes. The advantages of this box are that it provides a small, light, portable heat-bath for the hand, that it can be used anywhere where electric current is installed, and it provides a method which gives admirable results in clearing up infections of the hand and preventing adhesions of tendons and stiff hands.

RATIONS FOR EXPERIMENTAL AND DOMESTIC ANIMALS.

AT first sight it seems an easy task to construct a dietary for animals on which they can be maintained in good health over an indefinite period of time—a maintenance diet as Prof. R. G. LINTON calls it in the special article which we publish to-day. The problem is one which is of considerable importance to breeders of animals. It also is of interest to those who have to maintain large numbers of animals in field laboratories for experimental purposes. Since economic conditions enforce dietetic restrictions on man, the problem has also an important bearing on human dietetics. It is implied in the problem that the diet must be an economical one, and one which can be readily administered. The choice of foodstuffs is therefore limited and variations in the dietary are excluded. It is this absence of variety which introduces the difficulty, for almost any one of the common foodstuffs, except milk, will result, if given alone over a long enough period, in a deficiency of either specific amino acids or of certain inorganic elements or vitamins. Such a deficiency may not be so severe as to produce obvious ill-health or disease, and may only reveal itself if the animals are kept over very long periods of time by a diminished fertility, by increased susceptibility to infections, or by slight pathological changes which are only found post-mortem when looked for, such as the bone changes discovered in monkeys kept in the Zoo. At present our knowledge on these points is very imperfect because most experiments on dietetics have been carried out only over very short periods of time.

Experiments lasting over several generations of rats, such as those carried out by W. CRAMER and published recently in our columns,[1] seem to indicate that slight deficiencies may become cumulative when they are allowed to last over several generations. For such experiments the rat is a particularly suitable animal because it is short-lived, and several generations can be submitted to experiment in two years. It has also the advantage of being omnivorous.

Another difficulty in experiments on nutrition arises from the fact that observations made on one species do not necessarily apply to other species in every detail. Obviously, carnivorous animals such as dogs differ in their metabolism from purely herbivorous animals. In a discussion on diseases of nutrition in the Section of Comparative Medicine of the Royal Society of Medicine some months ago,[2] Prof. E. MELLANBY maintained, as a result of experiments on dogs, that cereals, and especially oats, contained something of a toxic nature. He went so far as to suggest that on theoretical grounds the diet usually given to race-horses was not well adapted to produce fast runners. There is an old proverb that one man's meat is another man's poison, and it may be that what is oats for a horse is poison for a dog.

When we come to such laboratory animals as rabbits and guinea-pigs, with which Prof. LINTON does not deal in his present article, the general experience is that excess of greenstuff, together with oats and middlings or wheaten bran, is good maintenance ration. In an interesting paper, E. BROOK and J. TREVAN[3] showed two years ago that guinea-pigs fed on a diet of mangold, bran, and oats, suffered from an epidemic which was due solely to the diet and could be counteracted by adding fresh greenstuff to the diet. Rats do well on a diet of bread and milk with the occasional addition of raw carrots, greenstuff, or kitchen scrap. Oats do not seem to agree with rats, at any rate they do not readily eat them, while mice thrive on them if they are given together with bread and occasionally a little greenstuff.

◆

ANTHELMINTICS.

DURING the last few years a vast amount of research has been published on the therapeutics, pharmacology, and chemistry of anthelmintics. Most of this is in connexion with the recognition of the great importance of hook-worm infestation in tropical countries and the necessity for a systematic campaign against it. Oil of chenopodium is the drug chiefly employed for this purpose. It is certainly effective against hook-worms, but its toxicity is rather high and the danger of this is increased by its variable composition. It was suggested by HALL and HAMILTON[4] that the toxicity of chenopodium oil was due chiefly to the less volatile fractions which contain a large proportion of an organic peroxide known as ascaridol, and that the more volatile fractions were found more efficient as an anthelmintic. They therefore suggested that it might be advisable to distil the oil and use only the more volatile fractions for therapeutic purposes. The work of HENRY and PAGET on the chemistry of chenopodium oil,[5] in conjunction with that of Dr. SMILLIE on its pharmacology and therapeutics,[6] shows, however, that the opposite is the case. The more volatile portion of the oil consists chiefly of terpenes of which cymene and α-terpinene are the more important, and the anthelmintic properties are attributed almost entirely to the ascaridol, the chief constituent of the less volatile fraction. This ascaridol is said to surpass the crude drug in safety and certainty of action. The reason of the discrepancy between these results and the previous work of HALL and HAMILTON is probably to be found in the instability of ascaridol on heating. If the distillation of the chenopodium oil is carried out at an insufficiently low pressure, there is a danger of decomposing the ascaridol so that the anthelmintic power of the oil is seriously impaired. In commercial samples of the oil thermal decomposition of the ascaridol may have taken place, and this may account for the wide variations observed in the ascaridol content (36–98 per cent.). In view of the dangers and toxicity of oil of chenopodium, some South American practitioners have abandoned its use altogether, while others suggest that it should only be administered when there are ample facilities for studying the case before and after administration. In this respect β-naphthol and thymol are advantageous, as they are readily obtained in a chemically pure condition, and though their anthelmintic power is considerably less than that of chenopodium oil or ascaridol, this is to some extent counterbalanced by their lower toxicity to the host and by the greater facility for exact dosage.

Recently, however, carbon tetrachloride has found a rapidly increasing favour in the treatment of hook-worm disease and threatens to replace oil of chenopodium, thymol, and β-naphthol for this purpose. Although it is definitely and strongly toxic, the balance of opinion appears to be that the therapeutic dose is safely below the danger-point. As it can be obtained in a comparatively high degree of purity it does not suffer, like chenopodium oil, from the defect of variable composition and uncertain dosage. Purity is an important essential, as impurities such as carbon bisulphide and phosgene are excessively toxic, the latter, in fact, being more poisonous than prussic acid. It is doubtful whether carbon tetrachloride acts as a true anthelmintic; more probably its action on the worm is that of a narcotic. On account of its poisonous action as an inhalation anæsthetic it should always be administered in hard gelatin or similar capsules so that it is liberated only in the intestines. It is claimed to be more efficient than chenopodium oil in the treatment of hook-worms and thread-worms. Although carbon tetrachloride has acquired a considerable vogue in the treatment of hook-worm diseases, its extreme toxicity should not be forgotten, and its action on the kidneys is a delayed one, so that it can hardly yet, in view of its short history, be regarded as a completely tried and safe drug. The economic factor has no doubt played a considerable part in its use for the wholesale treatment of hook-worms, as it is far cheaper than oil of chenopodium or thymol. It is probably this economic factor which has prevented a trial of santonin for the treatment of hook-worm disease. There appear to be no reports as to its action on these parasites, which is to be regretted, as it would be of great interest and scientific value to compare its action with that of chenopodium oil and carbon tetrachloride. Although its price at the present time might prevent its use in the large quantities required for this purpose, it, may, at some future date, be more readily available. For the ordinary round worms and thread-worms santonin is still the classical remedy. It has the advantage of being a definite chemical compound obtainable in a pure state, and hence capable of accurate dosage, and it differs from the great majority of anthelmintics in not being a gastro-intestinal irritant, so that it is specially useful where repeated doses of an anthelmintic are indicated.[7] Its toxicity is small compared with its therapeutic power, although the personal idiosyncrasy seems to vary a good deal, as it also does in the case of chenopodium oil. From experiments on worm musculature, the anthelmintic action of santonin is attributed by LAUTENSCHLÄGER[8] and by TRENDELENBURG[9] to the lactone ring in conjunction with the aromatic nucleus, open chain lactones being inactive. They found that simple cyclic lactones such as phthalide and meconin were as active as the more complex santonin, but there is no evidence that these simpler lactones are of any therapeutic value, and experiments on the muscles of non-parasitic worms are not a very safe guide to anthelmintic value. Very careful and elaborate experiments of this kind were made on earthworms by SOLLMAN,[10] but these and the experiments of LAUTENSCHLÄGER and TRENDELENBURG do not indicate the specific action of anthelmintics over certain worms, and therefore cannot explain, for example, why santonin is active against round worms and not against tape-worms, while male fern is active against tape-worms and not against round worms. Recently, a preparation called santoperonin was introduced, which claimed to be chemically analogous to santonin and to male fern, and to possess the therapeutic properties of both, but actually it has not the least chemical resemblance to either of them, and its anthelmintic and therapeutic properties are extremely doubtful.[11] As a remedy against tape-worms the so-called pelletierine tannate seems to be the best. It is not a definite chemical compound but is the precipitate obtained by the action of tannin on the extract of pomegranate bark, and is therefore a mixture of the tannates of the various alkaloids present in the bark.

The pharmacology of these anthelmintics is still in a very undeveloped state. Most phenolic substances, for example, have some anthelmintic action, and this is not surprising in view of their irritant and toxic character. Any irritant or toxic substance probably has some anthelmintic action, and if unabsorbed by the gastro-intestinal tract might have some therapeutic value, but it would not be a specific anthelmintic and would be therapeutically inferior to drugs such as santonin, male fern, and pelletierine. Carbon tetrachloride probably acts as a general poison in this way. With regard to santonin, two conflicting views are often quoted without comment in text-books of pharmacology. According to SCHROEDER, santonin expels round worms without killing them, and according to KUCHENMEISTER it kills them more rapidly than any other drug. This apparent discrepancy is probably due to the insolubility of santonin. In conjunction with oil, such as castor-oil, as in the experiments of KUCHENMEISTER, sufficient is apparently dissolved to kill the worms, whereas the minute trace dissolved in the absence of oil (SCHROEDER) is sufficient to expel the worms without killing them. From this it appears evident that santonin is a true anthelmintic with a specific action on the round worms. The same may be said of male fern and pelletierine. in respect of tape-worms, a concentration of 1 in 10,000 of pelletierine killing tape-worms in ten minutes. When it is realised how resistant these parasites are to most anthelmintics, this specific action is the more remarkable, and further investigation as to its mode of action would be of the greatest interest.

"Ne quid nimis."

ANNUAL MEETING OF THE B.M.A.

THE annual representative meeting of the British Medical Association opens to-day, Friday, July 18th, in the Examination Hall of the Technical College of Bradford, under the chairmanship of Dr. R. Wallace Henry. The printed agenda, which runs to nearly 150 items, includes such matters as indirect methods of advertising, legal liability in medical certification, and contributory schemes for private insured persons, which give promise of vigorous and profitable discussion. This meeting is expected to remain in session until Tuesday, July 22nd, when it is followed by the annual general meeting, at which the outgoing President, Mr. C. P. Childe, will induct his successor, Mr. J. Basil Hall, consulting surgeon to the Royal Infirmary, Bradford, who will then deliver the presidential address. The scientific sections will then meet concurrently on Wednesday, Thursday, and Friday, July 23rd–25th, and interesting subjects are set out on the provisional programme. The Section of Medicine, for instance, will take up cardiac irregularities, jaundice, and small-pox; the Section of Surgery will discuss acute osteomyelitis, pulmonary embolism, and auricular fibrillation; the Section of Pathology will have before it tissue culture, non-specific immunity, and protozoal intestinal affections. The annual dinner of the Association will take place at the Midland Hotel, at 7 P.M., on July 24th. A popular lecture on the Sun Cure will be delivered in the Mechanics' Institute by Sir Henry Gauvain on the evening of Friday, July 25th. The exhibition of surgical appliances, foods, drugs, and books, to be opened on July 22nd in the Windsor Halls, will give opportunity to members of the medical profession to see for the first time a number of new and ingenious inventions. The closing day of the meeting, Saturday, July 26th, has been set apart as usual for a variety of attractive excursions. The hon. local general secretary of the meeting is Dr. W. N. West Watson, Victor Lodge, Manningham, Bradford.

THE MEDICAL LESSONS OF A WAR.

THE last volume[1] of the Medical History of the Great War, which has just reached us, brings to a close a well-planned and quickly executed piece of valuable medical historical research. This volume merits the praise we gave to its predecessor[2]; it is a wonderfully clear statement of events as they occurred, compiled from a multitude of often conflicting reports from units involved in complicated and confused operations. It deals with many expeditions, each with its own trials: Gallipoli with its flies, the lack of water, and few hospital ships; Macedonia with malaria, mountains, and no roads; Mesopotamia with want of plan, and shortage of personnel and equipment; East Africa with its rain, tropical disease, and no natural main line of communications; Persia with its distance, its strange diseases, and thousands of refugees to feed, treat, and keep from spreading epidemics; Russia, a problem of swamps, snow, and uncertain allies. One outstanding lesson of this volume is that when an expedition is undertaken without careful consideration the first person to suffer is not the neglectful staff officer, though he may be brought to book later on, but the fighting man himself, who, because the medical corps has not been invited, nor given time, to do the best for him, gets unsatisfactory water or food when he is well, and not enough bearers or hospitals when he is sick or wounded. Were the staff, on active service, to take medical officers more into their confidence, telling them where and when the battle was to be, the wounded might be more quickly, more comfortably handled.

---

[1] History of the Great War. Medical Services. General History. Vol. IV. By Major-General Sir W. G. Macpherson, K.C.M.G., C.B., LL.D. London: H.M. Stationery Office. 1924. Pp. 711 + xvi. 25s.
[2] THE LANCET, May 24th, 1924, p. 1060.

All the Regular officers of the R.A.M.C. as they read this book will realise how great is their responsibility, for on them hinges the evacuation of the wounded, and it is they who must firmly claim, from those above them, the personnel and material, the transport, sanitary sections, or what not, without which they cannot do their best for the soldiers trusted to them. Sanitary sections should accompany the very first troops of any expedition; they prevent diseases. Civil practitioners will find (at p. 601) that army doctors are not doing surgical operations all the time, but that the most useful service a medical officer may have within his power to do for the sick may be to see how many of 300 camels he can get to a particular place and where each camel will be able to take two wounded to hospital, for every camel lost means two wounded delayed. The last chapter on transport by stretcher and ambulance is a record of wonderful ingenuity, evoked by the vastly different conditions of the various theatres of the war. In France the wounded were removed in trench stretchers, in the mountains of Macedonia in travois, camels carried them in Palestine, sand carts in Sinai, country boats and river steamers in Mesopotamia, hammocks in East Africa, sledges in Russia. Trains and motor ambulances were always the most desired, but horse-drawn ambulances, with teams of four horses, still proved of value, for they can travel over fields and rough ground cut up by shells, where no motor ambulance can move. Air transport of wounded is not mentioned, although we are told of a medical officer who was carried some hundred miles in a seaplane in Russia to see a patient. An unexpected discovery of the war was the particular suitability of the educated native of Uganda for work in the medical corps. Enlisted mainly from the mission schools, and subsequently given the status of soldiers, a thousand of them were employed in small parties from Abyssinia to Durban; their non-commissioned officers were found fit to be put in charge of large groups of porters in a native hospital. Praise is also given to the undaunted conduct of an Indian field ambulance at Gallipoli, of the Egyptian camels and their drivers on the Sinai desert, and to the travois mules in Macedonia, all unperturbed by shell fire. The maps and pictures in the volume are most helpful; the statistics of illness would be more enlightening if in every case the numbers were given of the troops to which they refer.

The volumes, indispensable as they are, are too many for any officer to carry in his kit. A short but pregnant résumé of the series, a sort of Medical Officers' Pocket Book, would serve to make the lessons of the last war, often so hardly learnt, available to those who will have to struggle with the difficulties of the next. Details may then be different, but principles must still count.

AN ENGLISH-SPEAKING OPHTHALMOLOGICAL CONVENTION.

IT has been decided by the Ophthalmological Society of the United Kingdom and its affiliated societies to hold in London next year a Convention of English-speaking ophthalmological societies and associations, and invitations have been issued to the presidents of all such bodies in the different parts of the British Empire and the United States of America asking them to appoint official delegates or representatives on the occasion. The date suggested is from July 14th to July 17th, inclusive, and the Convention will be inaugurated by a reception given by the President and Council of the Royal College of Surgeons of England at the College on the evening of July 13th. The programme for the four days' work has been already arranged. Each morning, two afternoons, and one evening will be occupied in the scientific work of the Convention. The Bowman Lecture will be delivered by Sir John Parsons, the chairman of the committee for scientific business and publication, there will be a discussion on the microscopy of the living eye, and selected speakers will also take part in a debate on the evolution of binocular vision. The rest of the time will be taken up by visits to various institutions of ophthalmological interest, while receptions have been arranged, a banquet and a garden party. Those taking part in the Convention who are not members of the Ophthalmological Society will pay a fee of £2, while for ladies accompanying members of the Convention, who wish to become associate members, the fee will be 10s. The President of the Convention is Mr. E. Treacher Collins, who can be addressed at 17, Queen Anne-street, London, W. 1.

THE STANDARDISATION OF DYSENTERY SERUM.

THE therapeutic value of antidysenteric serum is not a subject upon which anyone who had experience of epidemic dysentery during the war will have any doubts. Where serum was freely used excellent results generally followed. In most cases a polyvalent preparation was employed, and it is more than probable that had any monovalent serum been available even better results might have been obtained, since there is no definite evidence that the different types of dysentery bacilli produce a common and unique toxin. The standardisation of dysentery serum is a matter of some difficulty, and at the present time we are far from the realisation of the same accuracy of titration which is possible for diphtheria and tetanus antitoxins. The difficulties are both that of technique and that of inadequate information. We are unable to produce the same sharply marked animal results as with the two last-mentioned infections, and knowledge is hazy as to the undoubted toxicity of the dysentery bacillus. A recent work from the Kitasato Institute of Japan, published under the auspices of the League of Nations,[1] has made an attempt to narrow down the issues in this field, and to clarify the principles of the standardisation of dysentery serum. The authors of this paper concern themselves solely with the Shiga variety of bacillary dysentery, and as a first step towards the end in view have endeavoured to find out the best way of preparing a potent and stable dysentery toxin. They find that in broth cultures the toxicity rises pretty sharply for a couple of weeks and thereafter falls off again, the development of maximum toxicity corresponding to the development of a late alkalinity of the medium which reaches its maximum at about the same time as the toxin content. The toxin thus prepared is fairly stable, but by no means absolutely so. Its toxicity is well marked, 0·05–0·1 c.cm. being generally fatal to rabbits. It does not, however, appear to be as toxic as is an autolysed extract of the bacterial bodies. Having obtained adequately toxic preparations for the estimation of the protective powers of antitoxins, the authors proceeded to compare antisera prepared by the injection of a number of preparations. The experiments are not sufficiently numerous to give convincing results, but, with this proviso, it appears that serum obtained by injecting horses with fresh cultures of dysentery bacilli, suspended in saline, is likely to be more potent than that prepared by the injections of sterile toxins and broth cultures, both of which are more lethal to the animals than is the first-named preparation.

The actual standardisation of antitoxin was found to be fraught with great difficulties, not the least being the wide variation in individual susceptibility met with in the rabbits upon which the experiments were made. For example, one animal may be capable of withstanding several times the dose which is fatal to another animal of the same weight. In consequence of this the usual procedure of estimating the smallest amount of antitoxin required to neutralise a lethal dose of toxin was inapplicable and recourse was made to the method of estimating how much antiserum might be added to 20 average lethal doses of toxin without inhibiting its effect. In this way an estimate of the weakness of the serum is made rather than its strength. In spite of such modifications difficulty in making an exact estimation of the potency of the serum exists, although for practical purposes relatively accurate figures may probably be obtained. An attempt is made to separate the antibacterial and antitoxic powers of the serum, but with no very definite results, and it appears clear that further investigations are required to elucidate these two factors and the parts they play in the pathogenicity of *B. dysenteriæ*. It is interesting to note that the bacterial factor is the one most favoured for antiserum production, whilst a toxic filtrate is used in the estimation of serum potency. It would be well if more light were thrown upon the unity or individuality of these two factors. A further report upon the application of the findings of this first investigation to the standardisation of serum on a commercial scale is to be presented, as also are the results of its clinical employment.

INSANITY AND ART.

COMPARATIVELY few people know that lunatics paint pictures, hold their own exhibitions, and even have their work hung at the Royal Academy. These and many other interesting facts were told to the Art Lovers' League by Dr. T. B. Hyslop at Leighton House on July 8th, in a lecture entitled Disease in Modern Art. Dr. Hyslop, an artist as well as an alienist, confined his remarks almost entirely to the work of certified lunatics and showed a remarkable series of slides prepared from pictures which he had collected at Bethlem Hospital. Many of these illustrations showed no signs of disease, while others were mere jumbled masses representing people and other objects. One patient produced quite pleasing studies, but left out the faces of all his models. The progress of cerebral lesions was demonstrated in several sets of pictures. In one all objects became gradually more and more elongated, while in another the artist started by cutting the corners off his paintings and finally drew everything in circles which slowly diminished in size. At the close of his lecture Dr. Hyslop presented his valuable collection of lunatics' pictures and lantern slides to the Art Lovers' League.

CARE COMMITTEES FOR THE TUBERCULOUS.

THE Need and Organisation of Care Committees was the subject discussed at the final session of the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis reported in our last week's issue. Lieut.-Col. J. A. Ellis, B.Sc., who had undertaken to collect for the Association all available data on this subject, pointed out that in many areas the whole of the tuberculosis service was in the hands of a solitary tuberculosis officer, who would welcome the formation of a care committee. Neither he nor the general practitioner could undertake to go out looking for disease. As many cases came under observation at a late stage enlightenment and education of the public were required, and the local authority should provide not only sanatoriums for suitable cases but also accommodation for advanced ones. The problem is not so difficult in a self-contained community like a county borough or a town as in rural areas. In one area the local authority gives 25 per cent. additional to all money collected by voluntary subscription. The care committee should not be too insular nor should it avoid publicity. The personnel of the committee should be comprehensive and the principles guiding its activities should be both social and economic—the physical requirements in the home; education in hygiene, personal and communal; distribution of extra nourishment and clothing; coöperation with existing organisations, such as the National Health Insurance, War Pension Committees, &c., and the finding of employment—all these activities might be undertaken by care committees. In short, all anti-tuberculous work should be extensive, intensive, continuous, and timely; the advantages of publicity should not be neglected. A national survey of certain areas on the lines of the Framingham experiment[1] was recommended.

The discussion laid bare several difficulties of organisation. For example, to obtain information as to the existence of tuberculosis in a family among whom it is desired to place a child is not easy; to persuade employers to find work for the tuberculous is even harder. This is not surprising, for healthy men do not like working alongside the tuberculous for fear of infection. The dangers of asking too many questions and thus arousing hostility were emphasised by one speaker, and of conducting public health propaganda directed against one disease alone by another. Dr. Macdonald (Battersea) explained that in many places the care committee is a separate entity, divorced from the dispensary instead of being an indispensable part of it. His view was that if the care committee and the dispensary were adequately staffed, and one paid secretary acted for both, better coördination would result. Some speakers highly commended the work done by the care committee; others praised the good services of the health visitor, and held that money should be spent on the extension of this aspect of the work rather than on care committees. Adequate representation on every care committee, of friendly societies and of trade-unions, and a closer coöperation between medical and lay members was one of the suggestions made for increasing the value of these committees, which we can heartily endorse.

HEALTH IN THE COTTON INDUSTRY.

THE 1923 report of Dr. W. A. Daley, the medical officer of Blackburn, draws attention to the health of operatives in this centre of the cotton industry. Blackburn comes out well in comparison with other towns in housing matters; of 31,425 separate dwellings, 30,405 were occupied by one family only, and the percentage of persons living more than two to a room was the lowest in the county. The proportion of females to males, 1197 to 1000, is the largest of the industrial towns of Lancashire. During the last decade the total population has decreased; between 1911 and 1921 the number of male textile workers declined from 15,896 to 11,701, and of female from 25,913 to 24,999. One of the changes which has taken place is the increasing employment of married women in the cotton mills. Their numbers have risen from 9448 in 1911 to 9684 in 1921. Blackburn now has a larger proportion of married women industrially employed than any other Lancashire town—viz., 56 per cent. of those under 44 years of age and 22·9 per cent. of those over 44 years. Like other towns where married women are extensively employed in the factories, Blackburn has a low birth-rate, a high neonatal and infant mortality, and it is one of the towns specially referred to in Dr. Janet Campbell's recent report as showing year by year a very high mortality among mothers due to child-bearing. The number of stillbirths is also high, the rate for 1923 being 5·4 per 1000 registered live births, as compared with the average for the county of about three. Dr. Campbell says that return to work after the birth of a child is not as a rule long delayed, and that there is comparatively little breast-feeding. Rickets, she says, was very prevalent 20 to 40 years ago, and contracted pelvis is not uncommon in women from 20 to 40 years of age. It is not surprising to find that Dr. Daley associates the high maternal mortality from childbirth with the employment of so many married women in industrial occupations. It would seem likely that the high stillbirth-rate and the high death-rate of infants under one month and one year are due to the same cause. There is no need to labour the point that a low rate for breast-feeding means a high infant mortality-rate.

---

[1] See THE LANCET, 1924, i., 1243.

Another point affecting the health of the cotton operatives dealt with by Dr. Daley is of very great interest—namely, the effect on health of artificial humidity. He has been unable to compare the health of two populations of cotton operatives living and working under similar conditions with the one exception of the provision of artificial humidification of the work-place. Dr. Daley has, therefore, done the best he could by comparing the death-rates among various classes of cotton operatives who live in Blackburn and are subject to the same environmental and general conditions of life outside the mill. He divides the operatives into four classes—viz., weavers, spinners, winders and warpers, and card-room workers. Recent figures show that female weavers have the best vital statistics. The conclusion to be drawn from the figures, says Dr. Daley, is "that, *so far as the death-rates show, weaving in humid* sheds such as there are in Blackburn is healthier than the other branches of cotton manufacture as carried out in this town." This result is somewhat surprising in view of the teaching of Prof. Leonard Hill which is now being generally accepted. Dr. Daley suggests no explanation beyond the conjecture that the result may be due to the small amount of dust which is to be found in these humid atmospheres.

THE VAGARIES OF SURGICAL TUBERCULOSIS.

In the paper by Mr. R. V. Dolbey and Mr. A. W. Mooro, published in THE LANCET of June 7th, there is much evidence to show that surgical tuberculosis among the Egyptians differs considerably from the disease as we know it in this country. Tuberculosis in general—surgical tuberculosis in particular—is the greatest scourge in Egypt, and among the poor urban population 80 per cent. of the gross tuberculous disease of the bones, with abscesses and mixed infection, terminate fatally. As a rule, the disease takes about 18 months to kill. Little wonder therefore that amputation is regarded in Egypt as the safest and best functional operation for mixed infections of the limbs. If we compare this paper with one recently published by Mr. G. R. Girdlestone,[1] it is impossible to avoid the conclusion that not only does tuberculosis vary greatly in its behaviour in different countries, but that even the elementary principles underlying the treatment given in different institutions show a remarkable lack of uniformity. Does this lack of uniformity credit us with a versatility that is appropriate to a disease itself infinitely varied in its manifestations, or must we confess that the polymorphism of our treatment betrays ignorance of the fundamental requirements of the sufferer from surgical tuberculosis? It is exceedingly difficult to compare the merits of different treatments by the results obtained, for "results" are usually published too early and, as Mr. Girdlestone points out, "a cure in one hospital's register may be a very sick patient in another hospital's bed." In surgical, as well as in pulmonary tuberculosis, there seem to be differences of opinion as to the respective merits of mobilisation and immobilisation, and while Dr. Rollier of Leysin aims at mobility, many English surgeons are thankful if they can obtain immobility with permanent arrest of the disease. Again, in the matter of cold abscesses, Sir Henry Gauvain at Alton aspirates frequently and often injects alterative fluids, whereas Dr. Rollier and Mr. Girdlestone aspirate a cold abscess only when it threatens the skin. Many other instances could be given of divergencies of teaching in the most prominent tuberculosis centres throughout the world, and one may be inclined to suspect that the decline in the incidence and severity of tuberculosis in many civilised communities at the present time may not be solely due to the almost infinite ingenuity of man, but also to factors over which he has a very limited control. It is, indeed, almost impossible to avoid this conclusion when we compare the fate of the average patient in Egypt with that of his fellow sufferer in certain European countries.

THE LATE PROF. R. W. LOVETT.

We have already had occasion to chronicle the death in this country of Prof. R. W. Lovett, of Boston, U.S.A. Robert Williamson Lovett was born in 1859, and was a graduate both of Harvard College and the Harvard Medical School. At a comparatively early age he was appointed to the junior surgical staff of the Boston Children's Hospital, and for a time acted in a similar capacity at the Boston City Hospital. The latter association was a passing phase; it was the children's hospital which provided him with those special opportunities which he was to utilise with such great distinction. At the hospital Lovett was for some years the junior colleague of Dr. E. G. Bradford, who occupied the position of surgeon-in-chief, and who was first responsible for the somewhat revolutionary move of dividing the surgical side of the hospital into two services—one dealing exclusively with orthopædic surgery and the other embracing what was left over, and for want of a better term labelled "general surgical." This was the real beginning of the now renowned Boston school of orthopædic surgery, which was fortunate enough to earn local recognition at an early date in the form of the creation of a professorial chair in this subject at Harvard. Lovett succeeded to the chair after the retirement of Bradford, and continued to add to the prestige given it by his most distinguished senior colleague. Their names were inseparably coupled in the many activities concerned with the growth of a special surgical school. and particularly in connexion with the well-known text-book of orthopædic surgery which they published in the early 'nineties. When Lovett attained the rank of surgeon-in-chief to the Boston Children's Hospital he soon became its most dominant figure, and his influence and leadership were manifested in the wider spheres of hospital organisation, the affairs of the Harvard Medical School, and of American surgery. He was the absolute antithesis of the hospital surgeon endowed with technical ability and little else; his achievements emphasised again and again the futility of appointing to high executive positions either the pure craftsman or the academic scientist. Two years ago, when Lovett was prepared to relinquish the arduous duties of his hospital and teaching chair, it was felt that he could not be allowed to retire altogether as he was then at the zenith of his experience, influence, and power. His successor, Dr. R. B. Osgood, was appointed to both offices, but the chair was duplicated and the professorial title was still held by Lovett at the time of his tragic death. Lovett was a fine clinician and teacher and, above all, a master organiser. As an operator he was not naturally dexterous, but he took infinite pains and care with each operation, no matter how small, and thus was able to obtain very good results. It was his custom to pick out from time to time a series of cases of a given type and to operate on these himself, the experiences forming the basis of future critical pathological or end-result studies. But he distributed the large share of the operative work of his clinic to his associates. In consequence he was able to attract and—more important—to retain on his staff a group of comparatively senior men to whom he accorded a large measure of anatomy. In this respect he was the great surgical "Meister," but—happily for his associates—not in the accepted continental sense of the term. The communications to the literature of orthopædic surgery which have emanated from the Boston Children's Hospital bear witness to the strength of this type of surgical organisation. Lovett's own personal contributions were many and varied, but on the subject of scoliosis and infantile paralysis his knowledge was unrivalled. He began his observations on scoliosis many years ago, and he never lost his interest in a problem which to many has always seemed arid and, from a therapeutic point of view, insoluble. His monograph on this subject is, of course, classical. In 1916, when the epidemic of acute anterior poliomyelitis first assumed devastating proportions in certain of the Eastern States of America, Lovett's active mind at once turned from the conventional problem of the individual deformed patient of the later stages to the handling of patient en masse at the inception of the disease, with a view to the complete prevention of deformity. In the State of Vermont he was officially placed in control of the cases as they occurred, and early and correct treatment was instituted on a large scale. The Harvard Infantile Paralysis Commission was later organised to deal specially with adults attacked by this disease. From this unique clinical experience our knowledge has been enriched in a number of contributions published during the past few years and crystallised in the chapter on infantile paralysis in the great text-book which Lovett issued last year in collaboration with Sir Robert Jones, at whose house he died. Our sense of personal loss is heightened by the remembrance of Lovett's generosity in affording opportunities to some of the younger British surgeons of working in his clinic at Boston.

---

[1] Tubercle, July, 1924.

IT is announced in Army Orders that with effect from April 1st, 1925, the examination of majors of the Royal Army Medical Corps for promotion to lieutenant-colonels will consist of a written examination in army medical organisation and administration in peace and war, and of a medical staff tour.

A DANISH seaman with a black skin has recently been the subject of a very thorough investigation at Guy's Hospital. The condition which, although very rare, has been the object of previous study, is characterised by (1) exfoliative dermatitis, with progressive pigmentation of the skin; (2) intense hyperidrosis; (3) mental symptoms, of which delusions are the most frequent evidence. The mental condition of these patients impedes investigation of these cases in the wards of a general hospital.

Dr. David Murray Lyon has been appointed by the University Court of Edinburgh to be Christison Professor of Therapeutics in succession to Prof. J. C. Meakins, whose appointment as director of the medical clinic established through a grant of the Rockefeller Foundation in McGill University, Montreal, we announced recently. Prof. Murray Lyon was associated in his work with Prof. Meakins in the Royal Infirmary of Edinburgh, where he was appointed assistant physician in 1919.

INDEX TO "THE LANCET," VOL. I., 1924.

THE Index and Title-page to Vol. I., 1924, which was completed with the issue of June 28th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

THE LANCET OF FEB. 2ND, 1924.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXX.—TREATMENT OF MYOPIA IN YOUNG CHILDREN.

IT is astonishing how deep-rooted are the prejudices and old fallacies about myopia in the public mind and often, unfortunately, in the minds of many practitioners as well. The commonest of these is that short-sighted people get better as they get older, and that therefore myopic eyes are very "strong." Both these fallacies arise from the fact that it is generally considered a sign of weakness to be compelled to wear glasses, and since the presbyopic correction after 45 counteracts to a certain extent the myopic correction, myopes at and after this age usually find that they are able to read without glasses. Such reasoning seems entirely to ignore the fact that the distant vision remains exactly the same as it was before and depends for its perfection on the use of distance glasses, by which alone the degree of myopia can be measured. These fallacies tend to encourage parents to be careless in bringing their children for advice, or in carrying out the treatment, while it leads the practitioner to hesitate in expressing his opinion and sticking to it. It is therefore vitally important to bear in mind the many causes which contribute towards the development of myopia.

Causation.

There are various factors in the causation of myopia, but the commonest, at any rate in children, is what is known as axial myopia or abnormal length of the eyeball. This is sometimes congenital, but more often develops during the earlier years of child life, and is liable to increase up to the age of about 22. This lengthening of the eyeball takes place at the posterior pole of the eye, and if this distension occurs either quickly or gradually there comes a point when the choroid and retina, which should normally be closely adherent to the posterior part of the sclera, become thinned, split, and finally rent to such an extent that gaps are formed in these structures and so-called atrophic patches are found at the macula; the stretching round the optic nerve gives rise to the myopic crescent and staphyloma, often a useful guide to the degree of progression. Thus the vision is seriously affected. Also in after life the vitreous is liable to become fluid, the change being due either to inherent changes in its structure or to some interference with the character of the fluid secreted by the ciliary body; this may lead to shrinkage, and thus detachment of the retina is liable to occur following any excessive muscular effort, and occasionally the lens becomes opaque and cataract develops. In my experience it is not common for such serious pathological changes to happen in young life, but the progression takes place at this stage and the pathological changes may develop later. The very fact that the eyeball bulges posteriorly is evidence of weakness of the scleral envelope, which is probably due to defective nutrition for reasons connected with the health, but the determining factors which contribute to this distension is a subject of some difference of opinion. Although many arguments can be advanced against it, the generally accepted view is that close application to near work for a length of time is largely responsible; owing to the fact that the extra-ocular muscles are attached to the globe they are liable to press on the eye when put into action. No movement of the eyes is a simple one, and in order to maintain the eyes in one position for any length of time many of the muscles jointly take part in the action and a sustained pressure is thus induced. Reading at near range results in such combined action, and the muscular tension, being imparted to the eye in the presence of a weak sclera, encourages the posterior pole, which is unsupported, to give way. It is doubtful whether accommodation has much to do with the production of myopia, but the irregular accommodation required in astigmatism may have some influence. Progressive myopia may occur without the patient being aware of it unless he wears glasses regularly.

The possibility of the occurrence of all these changes and possible influences must be present in the practitioner's mind when he approaches a case of myopia in a child, however remote the changes may be, or however unlikely they appear to be at the time of the examination.

Symptoms.—There are very few symptoms associated with myopia. There is hardly ever any asthenopia unless the short sight is associated with some muscle-balance defect, and practically the only complaint that patients make is that they are unable to see properly in the distance. This is by no means always the case, as many myopes will express themselves perfectly satisfied with their distant vision, and often object to wearing glasses on this account.

Management of a Case.

In children the refractive error should be carefully measured under a mydriatic, and the glasses ordered should be the lowest strength with which the patient can see 6/6 binocularly. It will be found that this represents a strength slightly lower than is accepted monocularly. In no case should a myope be over-corrected; this is a serious error. On the other hand, the old prejudice against ordering full correction in cases of myopia of any degree is entirely unjustifiable. This fallacy is founded on the assumption that full correction glasses necessitates a full amount of accommodation for near work and that this conduces to progression. But it is doubtful whether accommodation plays any part in the causation of myopia, and in many myopes the accommodation is certainly as strong as in emmetropes, though in several cases of high degree it has been proved to be atrophic. Many people are perfectly happy in full correcting glasses, while others describe various discomforts from wearing them which they seem unable to ignore or get accustomed to. Each case must be judged on its merits. I always encourage patients to begin with full correction; the strength can always be reduced later if necessary.

Glasses should be worn constantly by myopic children, as by this means their visual acuity is maintained at full normal (if 6/6 vision has been obtained); they quickly become aware of any departures from this standard and thus become conscious of the first signs of progression; whereas the changes in visual acuity at near range are not so noticeable, as the necessity for reading at a slightly shorter range than has been customary does not make any impression. Full correcting glasses also enable children to read at the most suitable distance (viz., 12 to 18 in.) which they otherwise might not be able to do, and this is much less straining for the eyes. No reading glasses should ever be ordered in young people unless it is proved on examination that they are unable to read J. with their glasses and yet can see 6/6. This indicates that the accommodation is weak, and under these circumstances reading glasses may be ordered temporarily; when the power of accommodation improves they can be discarded.

Very high myopes almost always prefer not to have full correction, and often are not comfortable except with three or four dioptres less, but even in such cases a trial with full correction should be made, and some patients are anxious to wear such glasses. The only objection is the heavy weight of the glass in the spectacle frame. Parents are often very averse to their children wearing glasses, and myopes themselves are particularly disinclined to use them, even though they realise that their visual acuity will be improved thereby. Under such circumstances the practitioner must remain firm in his opinion, especially in the case of children.

The general advice given to myopic patients is directed towards preventing the constant application of any kind of near work for any length of time. A proper form of desk for writing purposes should be advocated, so that the patient is compelled to sit up and keep at a reasonable distance; a good light is essential, so as to avoid the alternative of putting books and work close to the eyes in order to secure a larger image, and no small print or fine needlework is permissible for the same reason. Reading in bed is not bad in itself, but only because the position of the light is usually utterly unsuitable for comfortable reading; lying on the side only causes the eyes to be maintained in an abnormal position and necessitates the unnatural muscular action which is so bad for myopes. It is an important matter to discourage continuous application in reading and sewing, but to arrange for definite periods of rest alternating with periods of work.

In cases of definite progression, such as one or two dioptres in six months, the question of discontinuing all reading and school work has to be decided, and this becomes a serious matter in children who have reached an important stage in their education, but before taking this serious step all pleasure reading can be forbidden as a preliminary measure. Near work need not be curtailed merely because a patient has high myopia; it is the signs of progression that matter. It is of the greatest importance in all cases of myopia in children to pay particular attention to the general health, since the weakness of the sclera must not be lost sight of as one of the predisposing causes. When high myopia has become stationary reading may be permitted but physical over-exertion must be avoided, as in this way detachment of the retina is encouraged.

THE MAINTENANCE RATIONS OF ANIMALS.

By R. G. Linton, M.R.C.V.S.,
DEPARTMENT OF HYGIENE, ROYAL (DICK) VETERINARY COLLEGE, EDINBURGH.

A maintenance ration may be described as that which will keep an animal that is in a resting non-producing condition and in good health in the same condition and at the same weight *for an indefinite period.* A diet that keeps an animal at a constant weight and *apparently* in good health for a short period is not necessarily a true maintenance ration. For example, certain monkeys kept in confinement in a zoo which are accustomed under natural conditions to a varied diet, including insects and grubs, may live for a considerable time in confinement on a diet of mixed fruits and nuts. When eventually these animals die, post-mortem examination not infrequently reveals a hitherto unsuspected osteomalacia, evidence that the diet has been deficient. It is therefore to be assumed that long before symptoms of illness became evident the animals had been living in a condition of "half-health," hence one would not be justified in regarding this diet as a maintenance ration, notwithstanding the fact that it does maintain life even to the extent of several years.

In connexion with the domesticated animals in many cases it is very difficult to say what really constitutes a true basal ration if it is agreed that the diet must maintain health for a long and not short period. There are many factors which have to be taken into consideration, any one of which, if neglected, may tend to lower the health-level of the animal. Every basal ration should be constructed so as to allow for sufficient exercise, as a certain minimum of exercise is essential if health is to be maintained. The writer, when feeding oats stained with methylene-blue to horses for the purpose of determining the rate of passage of food through the intestine, found that a few minutes' walking exercise round a yard caused the fæces to be evacuated several hours earlier than when the same animals were kept standing tied up in a stall. Dogs accustomed to regular exercise, and thus regular evacuation of the rectum and bladder, when kept confined in a cage fail to get rid of their waste products as soon as they should, and thus real health is not maintained. It is well known that cattle and horses when conveyed by ship, even for a short distance, show a gain in weight out of proportion to the amount of food they could have digested. This temporary increase in weight is due to the accumulation of indigestible food and waste products in the intestinal tract. This is a very important point to keep in mind when carrying out feeding experiments with animals confined in cages, for this delay in evacuation of residual matter, if continued for an appreciable period, is bound to have a detrimental effect on the health of the animals.

Requirements for a Basal Ration.

The requirements for a proper basal ration for animals may be summarised as follows: (1) The net caloric intake must be equivalent to the basal fasting katabolism, together with an allowance for the increased metabolism due to the specific dynamic action of the food consumed. (2) It must supply sufficient net energy for adequate exercise. (3) Additional metabolisable energy may be required simply for the purpose of supplying heat in the case of animals where the critical temperature is of practical importance. (4) There must be sufficient protein to equalise nitrogen outgo. (5) There must be sufficient "coarse" food in the ration to open out the concentrated food and thus allow the free access of digestive juices. (6) An adequate bulk to the ration is necessary to cause the optimum distension of the stomach and intestines necessary for proper digestion, and to give that sense of repletion without which the animal will not be contented. (7) The protein and non-protein constituents must be in proper proportion the one to the other, as also must the fat to the protein, for the optimum digestion of the food to take place. (8) There must be a properly balanced and sufficient mineral supply to ensure a normal ionic concentration. (9) The food must be suitable for the particular species of animal. (10) An adequate supply of vitamins is essential. (11) Finally, the food must be palatable.

Neglect to study the above points when formulating rations, especially when the object of feeding an animal is to conduct a feeding experiment, may be the cause of very misleading results, and it should be remembered that whilst animals possess a considerable flexibility in their capacity to utilise strange and unnatural foods, this power to acquire tolerance is not unlimited.

Maintenance Requirements of Horses and Cattle.

Maintenance requirements of farm animals are sometimes expressed in terms of *net energy*, which is equivalent to Kellner's production starch equivalent, or, on the other hand, in terms of *gross digestible energy*, which is equivalent to Armsby's *metabolisable energy*, or the so-called maintenance starch equivalent. The caloric value of 1 lb. of metabolisable energy expressed as starch is 1710 Kilo-calories (C.); that of 1 lb. of net energy expressed as production starch equivalent is 1071 C.

In accordance with our conception of a true basal maintenance ration, the requirements for the maintenance of a horse have been studied by many interested in animal nutrition. A critical study of the investigations that have been made to this end has been provided by Armsby in his "Nutrition of Farm Animals."[1] Armsby accepts the finding of Zunts and Hagemann, which is that for an animal weighing 1000 lb. there is required a total of 11,900 C. of metabolisable energy made up as follows:—

Net energy for internal work..	4,100 C.
Additional required for heat production	7,800 C.
Total metabolisable energy	11,900 C.

This caloric requirement is not taken to mean the physiological minimum but an economic minimum.

In 1917[2] I estimated the maintenance requirement for horses and, basing my calculations on a study of former investigations and on the rations given in practice, suggested that a total of 13,000 C. of metabolisable energy would meet the demands of a 1000 lb. horse—that is, a light draught horse—where the temperature of the surrounding air was not too low, and provided that the ration contained sufficient net energy for physiological purposes. It was also assumed that this 13,000 C. would allow for the minimum of exercise required to maintain health.

It would appear, however, to be very difficult, if, indeed, it is not even impossible, to fix with any high degree of accuracy the maintenance requirements of horses and to express them in terms of calories. This is so for two reasons: first, because there is such divergence between the findings of the various investigators as to what constitutes a maintenance ration; and, secondly, because we have but rudimentary knowledge of the real caloric value of the different foods for these animals, either when fed as single foods or in combination, as when a composite diet is given, as, for example, hay, straw, and grain. It is well known that the digestibility, and hence the net energy value, of foods varies according to the combination in which they are given.

When calculating the rations of horses, it has been commonly assumed that the same food has an equal value for both the ruminant and the horse, and though Kellner himself says that his "starch values" may be applied to both horses and ruminants, this is doubtful, at least with a number of foods. Indeed, Armsby gives a much higher value to some foods for the horse than he does for ruminants, so that as some people use Kellner's figures and some Armsby's, it is not surprising that conflicting results are obtained.

If we assume Kellner's deductions to be correct and that 6·6 lb. of "starch" will satisfy the demands of a resting horse weighing 1000 lb., then 16 lb. of "good" quality meadow hay will constitute a maintenance ration so far as its energy value is concerned, since this quantity of hay has a metabolisable energy of 12,483 C. and a net energy value of 5355 C. We know in practice that 16 lb. of hay is fully as much as an animal of this size could eat in a day. If we refer to any published tables of food values we find that, while it is stated that 16 lb. of "good" meadow hay has a net energy value of 5355 C., an equal quantity of "very good" meadow hay has a net value of 6954 C. So that here we have a difference of 1600 C. in a diet of 16 lb. of hay, according to whether the feeder classes it as good or very good. To illustrate still further what confusion exists regarding food values for animals and their application when an attempt is made to construct a diet on "scientific" lines, we may refer to an example of a maintenance ration for a bullock given by Prof. T. B. Wood in his recently published "Animal Nutrition."[3] On p. 169 Wood quotes Kellner's figure for the net energy value of barley straw at 209 C. per lb. and Armsby's figure at 366 C. per lb. Accepting the latter figure which, as he says, was determined much more recently, Wood considers that 17 lb. of barley straw will supply sufficient net energy for the maintenance requirements of a 9 cwt. bullock, that is, 6000 C. of net energy. (This ration is, of course, deficient in protein, as Wood points out.) In subsequent pages, when compounding rations containing barley straw for bullocks, Wood makes use of Armsby's figure, but in his table of food values leaves the agriculturist to construct his rations from Kellner's figure which is the one, rightly or wrongly, that is in general use. What this difference in values means is made clear when it is understood that if Armsby's figure is used then 16·5 lb. of barley straw will presumably supply the 6000 Calories required, and if Kellner's be utilised, then no less than 28·7 lb. will be necessary. If Armsby's figure is right then Kellner's must of necessity be wrong, and as dairymen have been in the habit of constructing "scientific" rations for their cows from Kellner's figures they will be accommodation has much to do with the production of myopia, but the irregular accommodation required in astigmatism may have some influence. Progressive myopia may occur without the patient being aware of it unless he wears glasses regularly.

The possibility of the occurrence of all these changes and possible influences must be present in the practitioner's mind when he approaches a case of myopia in a child, however remote the changes may be, or however unlikely they appear to be at the time of the examination.

Symptoms.—There are very few symptoms associated with myopia. There is hardly ever any asthenopia unless the short sight is associated with some muscle-balance defect, and practically the only complaint that patients make is that they are unable to see properly in the distance. This is by no means always the case, as many myopes will express themselves perfectly satisfied with their distant vision, and often object to wearing glasses on this account.

Management of a Case.

In children the refractive error should be carefully measured under a mydriatic, and the glasses ordered should be the lowest strength with which the patient can see 6/6 binocularly. It will be found that this represents a strength slightly lower than is accepted monocularly. In no case should a myope be over-corrected; this is a serious error. On the other hand, the old prejudice against ordering full correction in cases of myopia of any degree is entirely unjustifiable. This fallacy is founded on the assumption that full correction glasses necessitates a full amount of accommodation for near work and that this conduces to progression. But it is doubtful whether accommodation plays any part in the causation of myopia, and in many myopes the accommodation is certainly as strong as in emmetropes, though in several cases of high degree it has been proved to be atrophic. Many people are perfectly happy in full correcting glasses, while others describe various discomforts from wearing them which they seem unable to ignore or get accustomed to. Each case must be judged on its merits. I always encourage patients to begin with full correction; the strength can always be reduced later if necessary.

Glasses should be worn constantly by myopic children, as by this means their visual acuity is maintained at full normal (if 6/6 vision has been obtained); they quickly become aware of any departures from this standard and thus become conscious of the first signs of progression; whereas the changes in visual acuity at near range are not so noticeable, as the necessity for reading at a slightly shorter range than has been customary does not make any impression. Full correcting glasses also enable children to read at the most suitable distance (viz., 12 to 18 in.) which they otherwise might not be able to do, and this is much less straining for the eyes. No reading glasses should ever be ordered in young people unless it is proved on examination that they are unable to read J. with their glasses and yet can see 6/6. This indicates that the accommodation is weak, and under these circumstances reading glasses may be ordered temporarily; when the power of accommodation improves they can be discarded.

Very high myopes almost always prefer not to have full correction, and often are not comfortable except with three or four dioptres less, but even in such cases a trial with full correction should be made, and some patients are anxious to wear such glasses. The only objection is the heavy weight of the glass in the spectacle frame. Parents are often very averse to their children wearing glasses, and myopes themselves are particularly disinclined to use them, even though they realise that their visual acuity will be improved thereby. Under such circumstances the practitioner must remain firm in his opinion, especially in the case of children.

The general advice given to myopic patients is directed towards preventing the constant application of any kind of near work for any length of time. A proper form of desk for writing purposes should be advocated, so that the patient is compelled to sit up and keep at a reasonable distance; a good light is essential, so as to avoid the alternative of putting books and work close to the eyes in order to secure a larger image, and no small print or fine needlework is permissible for the same reason. Reading in bed is not bad in itself, but only because the position of the light is usually utterly unsuitable for comfortable reading; lying on the side only causes the eyes to be maintained in an abnormal position and necessitates the unnatural muscular action which is so bad for myopes. It is an important matter to discourage continuous application in reading and sewing, but to arrange for definite periods of rest alternating with periods of work.

In cases of definite progression, such as one or two dioptres in six months, the question of discontinuing all reading and school work has to be decided, and this becomes a serious matter in children who have reached an important stage in their education, but before taking this serious step all pleasure reading can be forbidden as a preliminary measure. Near work need not be curtailed merely because a patient has high myopia; it is the signs of progression that matter. It is of the greatest importance in all cases of myopia in children to pay particular attention to the general health, since the weakness of the sclera must not be lost sight of as one of the predisposing causes. When high myopia has become stationary reading may be permitted but physical over-exertion must be avoided, as in this way detachment of the retina is encouraged.

THE MAINTENANCE RATIONS OF ANIMALS.

By R. G. Linton, M.R.C.V.S.,
DEPARTMENT OF HYGIENE, ROYAL (DICK) VETERINARY COLLEGE, EDINBURGH.

A MAINTENANCE ration may be described as that which will keep an animal that is in a resting non-producing condition and in good health in the same condition and at the same weight *for an indefinite period.* A diet that keeps an animal at a constant weight and *apparently* in good health for a short period is not necessarily a true maintenance ration. For example, certain monkeys kept in confinement in a zoo which are accustomed under natural conditions to a varied diet, including insects and grubs, may live for a considerable time in confinement on a diet of mixed fruits and nuts. When eventually these animals die, post-mortem examination not infrequently reveals a hitherto unsuspected osteomalacia, evidence that the diet has been deficient. It is therefore to be assumed that long before symptoms of illness became evident the animals had been living in a condition of "half-health," hence one would not be justified in regarding this diet as a maintenance ration, notwithstanding the fact that it does maintain life even to the extent of several years.

In connexion with the domesticated animals in many cases it is very difficult to say what really constitutes a true basal ration if it is agreed that the diet must maintain health for a long and not short period. There are many factors which have to be taken into consideration, any one of which, if neglected, may tend to lower the health-level of the animal. Every basal ration should be constructed so as to allow for sufficient exercise, as a certain minimum of exercise is essential if health is to be maintained. The writer, when feeding oats stained with methylene-blue to horses for the purpose of determining the rate of passage of food through the intestine, found that a few minutes' walking exercise round a yard caused the fæces to be evacuated several hours earlier than

380 g. of dog biscuit contains 63 g. of protein, it might be assumed that the biscuits by themselves would constitute a complete food, at least for adult dogs, but experience has shown us that excellent health is maintained when the above quantity of horse-flesh is added to the biscuits. It is also to be assumed that a proportion of the mutton greaves or "cracklings" is not digested by the dog, but at the same time it will serve a useful purpose by supplying bulk to the ration and to some extent take the place of the bones and more or less indigestible skin, some of which is, no doubt, consumed by the dog in its natural state. The albuminoid ratio of Dechambre's ration for the resting dog of 27 kilos is 1 to 6; that of this College, calculated from the chemical analysis, is 1 to 2·7 (the albuminoid ratio of bitch's milk is 1 to 2·2.

It is not suggested that either the ration of Dechambre or that in use here would be suitable for nursing bitches or growing pups. To make the diet complete, bones should be added and the best for this purpose are soft calf bones or the rib bones of lambs, which are easily masticated and digested. Rabbit, game, and poultry bones are to be avoided owing to their splintery nature and the frequency with which they cause serious intestinal lacerations. Though under more natural conditions, such as on farms, dogs possess the capacity to digest these splintery bones without apparently doing them any harm, house-dogs certainly have little power to do so. Some bulky food that is not so readily digested as flesh is an essential constituent of a maintenance ration for the dog, otherwise the excretion of waste products is delayed. Bones, furthermore, are very desirable in order to stiffen and harden the fæces and thus cause evacuation of the anal glands when the rectum is emptied.

In regard to the utilisation of *raw* flesh as part of the normal healthy dog's ration, this would not seem to be necessary. On the other hand, clinical experience has shown us that many cases of eczema in the dog are cured simply by making a complete change in the diet, withholding all carbonaceous food and giving raw flesh only. The potato above all foods seems to give the worst results, and in the opinion of many of us is responsible for a considerable amount of intestinal irritation and cutaneous lesions of an eczematous nature. Excessive feeding with porridge to house-dogs deprived of sufficient exercise also seems to be accountable for some of these troublesome conditions.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

The fifteenth annual meeting of the Oxford Ophthalmological Congress took place in the Department of Human Anatomy, Keble College, on July 3rd, 4th, and 5th, and during the greater part of the session was presided over by the Master, Sir Anderson Critchett.

Dr. E. Landolt (Paris) initiated a discussion on the

General Principles of the Treatment of Convergent Concomitant Strabismus.

He said that strabismus meant a vicious relative direction of the two eyes. To secure normal sight the visual lines of the two eyes should be directed simultaneously upon the point which at the moment the person was interested in; the accomplishment of this meant the use of binocular vision. It demanded, therefore, that the image of the object being looked at be formed at the same moment on both foveæ. When binocular vision was not operative in an individual, the cause might be a central one, but in most cases it was due to visual impairment of one of the eyes. The absence of binocular vision was the chief cause of the occurrence of concomitant strabismus. In concomitant strabismus the visual lines crossed either beyond or within the point fixed by one of the eyes. In the former event the squint was divergent (relative or absolute), in the latter it was convergent. When binocular vision was not in operation other influences played a part in determining the relative direction of the two eyes. The first important influence was the direction of the eyes in a state of absolute rest, which was a divergent direction; hence a divergent squint was a passive squint. The second influence was an excessive stimulus to convergence, and therefore this was an active squint, and it might be produced by some special alteration of the nerve centres. It was mostly due, however, to the relationship between convergence and accommodation, an unusual effort to accommodate calling forth excessive convergence. As convergence depended only on the distance of the fixed point, it was the same for all eyes; but accommodation depended also upon the refraction of the eyes. Eyes whose refraction was defective, especially those which were hypermetropic, had to provide a greater amount of accommodation than of convergence, and when binocular vision was not operative the convergence followed the impulse of the accommodation. One eye saw the object distinctly, and the excess of convergence was manifest only in the other eye.

With regard to treatment, the first aim should be to restore binocular vision. This could be done by correcting the optical errors, and particularly the errors of the deviating eye, and in the second place, by isolated visual exercises of this eye and orthoptic exercises of both eyes. Convergent squint required that the spasm of accommodation should be subdued, by such means as the use of mydriatics, the wearing of convex glasses, and giving the eyes rest. If orthoptic treatment failed, surgery would cure the squint—i.e., advancement of the external recti with resection of the extremity of the muscles. He did not advocate surgery to replace the other means, but to complete them.

Dr. E. Thomson devoted his contribution mainly to setting out the measures to be taken for the prevention of the development of the squint. After strabismus had commenced optical correction should be carried out at the earliest possible moment. He reminded members of the cadaveric position of the eyes, their physiological position, and compared these with the position taken up by them in strabismus. He also discussed amblyopia in relation to squint and its incidence and course in children.

The Master, in expressing his high appreciation of both contributions, said he fully recognised the merits of advancement over the former method, of which latter his father was the originator.

Dr. De Schweinitz agreed in the main with Dr. Landolt's contentions. He gave some interesting details of his methods in his Philadelphia clinic.

Mr. T. Harrison Butler said that during the last 18 months he had made muscle recession combined with advancement his sole operation. The failures were of two kinds—failure to correct convergence, and failure to correct divergence. He was referring only to squints of 30° and more. One of the causes of failure after operation was that the powerful internal rectus was continually pulling against the sutures. By detaching the muscle and attaching it to the sclera 4 mm. back the operation was half done, and his results had been much better. He commented on the prevalence of squint among the children of the poor, in contrast with that in the children of the better classes.

Dr. Beatson Hird gave some experiences of his work as ophthalmic surgeon to the City of Birmingham Education Committee. He said the cases of squint

perturbed at finding their careful calculations liable to so great an error.

Fallacies to be Avoided.

Attention is drawn to the above simply for the purpose of emphasising the danger of utilising values that are assumed to be correct. When we consider still further the great variation that exists in the quality of the foods given to animals, the divergence in views among those who have studied animal nutrition as to the energy required for maintenance, the fact that in many instances food values, such as they are, for ruminants are assumed to be applicable to the horse and, indeed, even to the pig, and many other conflicting assumptions, one is naturally led to ask, how is one to determine what are maintenance rations for the various domesticated animals? It would appear to be necessary before conducting a feeding experiment for the purpose of determining a fine point in animal nutrition to find out the maintenance requirements for each animal for the particular food used. This can only be done by careful and prolonged experiment.

Having determined the maintenance requirements of an animal of any given weight, those for other animals of the same species but different weights may be calculated approximately by means of the well-known surface law of Rubner. Though not sufficiently accurate for experimental work, this method may be applied to every-day use provided that it is not interpreted too literally. A considerable margin for error must be allowed. Estimates of the weights of horses are often exaggerated. The writer found the weight of British army horses in good hard-working condition, not fat, to be as follows: Heavy draught mules 1350 lb., heavy draught horses 1300 lb., light draught horses 1150 lb., light draught mules 1100 lb., riders first class 1075 lb., and riders second class 975 lb. The average weight of heavy draught horses kept in a fatter condition than those in the army is 14 cwt. It is an exceptional animal that weighs over 16 cwt., though some approach a ton in weight.

A maintenance ration for horses that in the past few years has been well tested is that laid down by the Ministry of Agriculture for horses exported from this country to Europe. For horses of the larger type this is 15–20 lb. per day, for smaller animals 10–15 lb., and for small ponies and asses 5–10 lb. The average weight of these animals, excluding small ponies, is 11 cwt. Some few months ago the writer had a consignment of 22 horses weighed immediately before embarkation and again immediately after disembarkation at Antwerp. Every horse showed a marked increase in weight, and while, as stated before, this increase is in part undoubtedly due to incomplete evacuation of the intestinal tract, it at least indicates that the quantity of hay consumed was not below maintenance requirements.

The Maintenance Ration of Dogs.

The constitution of a healthy dog's normal maintenance ration has received much consideration from veterinary surgeons. It might be thought that the natural diet of the wild dog—flesh, blood, fat, and bones—would also be suitable for dogs kept in partial confinement under domestic conditions. Such a diet, however, is not economical, and experience has shown that it is not necessary. It has also been found that an exclusive diet of flesh does not give as good results as a mixed diet containing a proportion of carbohydrate for dogs doing hard and prolonged work, such as hounds and sheep-dogs, notwithstanding the fact that the dog is naturally a carnivorous feeder. Pariah or scavenger dogs of the East are, as is well known, omnivorous feeders, of necessity if not by choice.

A good test of the efficiency of a maintenance ration for dogs kept in more than usual confinement can be made with the diet allowed to dogs kept in quarantine for a six months' period. Many dogs representing most breeds have passed through the quarantine kennels of the Royal (Dick) Veterinary College. The amount of exercise is limited to bi-daily freedom of half an hour or so in an open court. With the exception of one dog, a West Highland terrier, which arrived with an eczematous condition of its skin, all the animals have completed the six months' period in excellent health and without becoming fat. The daily ration of these dogs consists of dog biscuits and horse-flesh. The dog biscuits are made from bakers' "seconds," mutton greaves ("cracklings"), and boiled horse-flesh, to which is added a percentage of salt. The horse flesh is obtained from healthy horses that have been shot and bled. The ration is divided into two parts; in the morning a dog biscuit is given dry and at 4 P.M. a larger feed is given consisting of broken biscuits soaked in hot water and mixed with par-boiled horse-flesh. The heavy feed is given in the evening in order to keep the dogs quiet during the night. From our experience we conclude that it is better to feed dogs twice during the day instead of once according to the popular idea.

The allowance for an Airedale or collie, weighing approximately 27 kilos, was weighed and analysed. The dog biscuit weighed 380 g., and the fresh unboiled horse-flesh 170 g. The analysis of each was found to be as shown in Table I.

TABLE I.—*Analysis of Dog Biscuit and Horse-Flesh.*

—	Biscuit.	Horse-flesh.	Total in ration.
	Per cent.	Per cent.	Grammes.
Water	15·73	74·94	—
Fat	2·28	2·60	13
Albuminoids	16·62	21·00	99
Carbohydrates	62·89	—	239
Fibre	1·10	—	—
Ash	1·38	1·08	—
Not accounted for.. ..	—	0·38	—
	100·00	100·00	351

For the above analyses the writer is indebted to his colleague, Prof. G. H. Gemmell, F.I.C.

This ration, which the clinical department of this College has found by experience to be suitable for adult dogs weighing about 24 kilos and not getting more than sufficient exercise to keep them in good health, was fixed upon without reference to any former investigation undertaken to determine a satisfactory diet. It is, therefore, particularly interesting to compare it with the rations for dogs suggested by Dechambre.[4] Dechambre published the results of his investigations in 1919, and stated that he considers that maintenance requirements for the dog can be calculated according to the surface law, as is the case with other animals. He published a table setting out the maintenance rations for dogs from 5 to 100 kilos in weight and also gave rations suitable for dogs doing moderate and hard work. For a dog of 27 kilos, such as an Airedale or collie, he allows for maintenance: Protein 55 g., fat 15 g., and carbohydrate 300 g., giving a total of 388 nutritive units reckoned on the formula (total protein + total carbohydrate + total fat × 2·2). The compared rations in grammes, therefore, are as given in Table II.

TABLE II.—*Prepared Ration in Grammes.*

—	Protein.	Fat.	Carbohydrate.	Total nutritive units.
Dechambre ..	55	15	300	388
R. (D.) V. C. ..	99	13	239	367
Difference ..	+44	−2	−61	−21

A comparison of these two rations shows that there is a close similarity in the total nutritive units supplied, but the diet given in this College contains nearly twice as much protein as that recommended by Dechambre and considerably less carbohydrate. The total protein allowed by Dechambre for hard-working dogs of 27 kilos weight is 100 g. As the

380 g. of dog biscuit contains 63 g. of protein, it might be assumed that the biscuits by themselves would constitute a complete food, at least for adult dogs, but experience has shown us that excellent health is maintained when the above quantity of horse-flesh is added to the biscuits. It is also to be assumed that a proportion of the mutton greaves or "cracklings" is not digested by the dog, but at the same time it will serve a useful purpose by supplying bulk to the ration and to some extent take the place of the bones and more or less indigestible skin, some of which is, no doubt, consumed by the dog in its natural state. The albuminoid ratio of Dechambre's ration for the resting dog of 27 kilos is 1 to 6; that of this College, calculated from the chemical analysis, is 1 to 2·7 (the albuminoid ratio of bitch's milk is 1 to 2·2.

It is not suggested that either the ration of Dechambre or that in use here would be suitable for nursing bitches or growing pups. To make the diet complete, bones should be added and the best for this purpose are soft calf bones or the rib bones of lambs, which are easily masticated and digested. Rabbit, game, and poultry bones are to be avoided owing to their splintery nature and the frequency with which they cause serious intestinal lacerations. Though under more natural conditions, such as on farms, dogs possess the capacity to digest these splintery bones without apparently doing them any harm, house-dogs certainly have little power to do so. Some bulky food that is not so readily digested as flesh is an essential constituent of a maintenance ration for the dog, otherwise the excretion of waste products is delayed. Bones, furthermore, are very desirable in order to stiffen and harden the fæces and thus cause evacuation of the anal glands when the rectum is emptied.

In regard to the utilisation of *raw* flesh as part of the normal healthy dog's ration, this would not seem to be necessary. On the other hand, clinical experience has shown us that many cases of eczema in the dog are cured simply by making a complete change in the diet, withholding all carbonaceous food and giving raw flesh only. The potato above all foods seems to give the worst results, and in the opinion of many of us is responsible for a considerable amount of intestinal irritation and cutaneous lesions of an eczematous nature. Excessive feeding with porridge to house-dogs deprived of sufficient exercise also seems to be accountable for some of these troublesome conditions.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE fifteenth annual meeting of the Oxford Ophthalmological Congress took place in the Department of Human Anatomy, Keble College, on July 3rd, 4th, and 5th, and during the greater part of the session was presided over by the Master, Sir Anderson Critchett.

Dr. E. Landolt (Paris) initiated a discussion on the

General Principles of the Treatment of Convergent Concomitant Strabismus.

He said that strabismus meant a vicious relative direction of the two eyes. To secure normal sight the visual lines of the two eyes should be directed simultaneously upon the point which at the moment the person was interested in; the accomplishment of this meant the use of binocular vision. It demanded, therefore, that the image of the object being looked at be formed at the same moment on both foveæ. When binocular vision was not operative in an individual, the cause might be a central one, but in most cases it was due to visual impairment of one of the eyes. The absence of binocular vision was the chief cause of the occurrence of concomitant strabismus. In concomitant strabismus the visual lines crossed either beyond or within the point fixed by one of the eyes. In the former event the squint was divergent (relative or absolute), in the latter it was convergent. When binocular vision was not in operation other influences played a part in determining the relative direction of the two eyes. The first important influence was the direction of the eyes in a state of absolute rest, which was a divergent direction; hence a divergent squint was a passive squint. The second influence was an excessive stimulus to convergence, and therefore this was an active squint, and it might be produced by some special alteration of the nerve centres. It was mostly due, however, to the relationship between convergence and accommodation, an unusual effort to accommodate calling forth excessive convergence. As convergence depended only on the distance of the fixed point, it was the same for all eyes; but accommodation depended also upon the refraction of the eyes. Eyes whose refraction was defective, especially those which were hypermetropic, had to provide a greater amount of accommodation than of convergence, and when binocular vision was not operative the convergence followed the impulse of the accommodation. One eye saw the object distinctly, and the excess of convergence was manifest only in the other eye.

With regard to treatment, the first aim should be to restore binocular vision. This could be done by correcting the optical errors, and particularly the errors of the deviating eye, and in the second place, by isolated visual exercises of this eye and orthoptic exercises of both eyes. Convergent squint required that the spasm of accommodation should be subdued, by such means as the use of mydriatics, the wearing of convex glasses, and giving the eyes rest. If orthoptic treatment failed, surgery would cure the squint—i.e., advancement of the external recti with resection of the extremity of the muscles. He did not advocate surgery to replace the other means, but to complete them.

Dr. E. Thomson devoted his contribution mainly to setting out the measures to be taken for the prevention of the development of the squint. After strabismus had commenced optical correction should be carried out at the earliest possible moment. He eminded members of the cadaveric position of the eyes, their physiological position, and compared these with the position taken up by them in strabismus. He also discussed amblyopia in relation to squint and its incidence and course in children.

The Master, in expressing his high appreciation of both contributions, said he fully recognised the merits of advancement over the former method, of which latter his father was the originator.

Dr. De Schweinitz agreed in the main with Dr. Landolt's contentions. He gave some interesting details of his methods in his Philadelphia clinic.

Mr. T. Harrison Butler said that during the last 18 months he had made muscle recession combined with advancement his sole operation. The failures were of two kinds—failure to correct convergence, and failure to correct divergence. He was referring only to squints of 30° and more. One of the causes of failure after operation was that the powerful internal rectus was continually pulling against the sutures. By detaching the muscle and attaching it to the sclera 4 mm. back the operation was half done, and his results had been much better. He commented on the prevalence of squint among the children of the poor, in contrast with that in the children of the better classes.

Dr. Beatson Hird gave some experiences of his work as ophthalmic surgeon to the City of Birmingham Education Committee. He said the cases of squint

perturbed at finding their careful calculations liable to so great an error.

Fallacies to be Avoided.

Attention is drawn to the above simply for the purpose of emphasising the danger of utilising values that are assumed to be correct. When we consider still further the great variation that exists in the quality of the foods given to animals, the divergence in views among those who have studied animal nutrition as to the energy required for maintenance, the fact that in many instances food values, such as they are, for ruminants are assumed to be applicable to the horse and, indeed, even to the pig, and many other conflicting assumptions, one is naturally led to ask, how is one to determine what are maintenance rations for the various domesticated animals? It would appear to be necessary before conducting a feeding experiment for the purpose of determining a fine point in animal nutrition to find out the maintenance requirements for each animal for the particular food used. This can only be done by careful and prolonged experiment.

Having determined the maintenance requirements of an animal of any given weight, those for other animals of the same species but different weights may be calculated approximately by means of the well-known surface law of Rubner. Though not sufficiently accurate for experimental work, this method may be applied to every-day use provided that it is not interpreted too literally. A considerable margin for error must be allowed. Estimates of the weights of horses are often exaggerated. The writer found the weight of British army horses in good hard-working condition, not fat, to be as follows: Heavy draught mules 1350 lb., heavy draught horses 1300 lb., light draught horses 1150 lb., light draught mules 1100 lb., riders first class 1075 lb., and riders second class 975 lb. The average weight of heavy draught horses kept in a fatter condition than those in the army is 14 cwt. It is an exceptional animal that weighs over 16 cwt., though some approach a ton in weight.

A maintenance ration for horses that in the past few years has been well tested is that laid down by the Ministry of Agriculture for horses exported from this country to Europe. For horses of the larger type this is 15–20 lb. per day, for smaller animals 10–15 lb., and for small ponies and asses 5–10 lb. The average weight of these animals, excluding small ponies, is 11 cwt. Some few months ago the writer had a consignment of 22 horses weighed immediately before embarkation and again immediately after disembarkation at Antwerp. Every horse showed a marked increase in weight, and while, as stated before, this increase is in part undoubtedly due to incomplete evacuation of the intestinal tract, it at least indicates that the quantity of hay consumed was not below maintenance requirements.

The Maintenance Ration of Dogs.

The constitution of a healthy dog's normal maintenance ration has received much consideration from veterinary surgeons. It might be thought that the natural diet of the wild dog—flesh, blood, fat, and bones—would also be suitable for dogs kept in partial confinement under domestic conditions. Such a diet, however, is not economical, and experience has shown that it is not necessary. It has also been found that an exclusive diet of flesh does not give as good results as a mixed diet containing a proportion of carbohydrate for dogs doing hard and prolonged work, such as hounds and sheep-dogs, notwithstanding the fact that the dog is naturally a carnivorous feeder. Pariah or scavenger dogs of the East are, as is well known, omnivorous feeders, of necessity if not by choice.

A good test of the efficiency of a maintenance ration for dogs kept in more than usual confinement can be made with the diet allowed to dogs kept in quarantine for a six months' period. Many dogs representing most breeds have passed through the quarantine kennels of the Royal (Dick) Veterinary College. The amount of exercise is limited to bi-daily freedom of half an hour or so in an open court. With the exception of one dog, a West Highland terrier, which arrived with an eczematous condition of its skin, all the animals have completed the six months' period in excellent health and without becoming fat. The daily ration of these dogs consists of dog biscuits and horse-flesh. The dog biscuits are made from bakers' "seconds," mutton greaves ("cracklings"), and boiled horse-flesh, to which is added a percentage of salt. The horse flesh is obtained from healthy horses that have been shot and bled. The ration is divided into two parts; in the morning a dog biscuit is given dry and at 4 P.M. a larger feed is given consisting of broken biscuits soaked in hot water and mixed with par-boiled horse-flesh. The heavy feed is given in the evening in order to keep the dogs quiet during the night. From our experience we conclude that it is better to feed dogs twice during the day instead of once according to the popular idea.

The allowance for an Airedale or collie, weighing approximately 27 kilos, was weighed and analysed. The dog biscuit weighed 380 g., and the fresh unboiled horse-flesh 170 g. The analysis of each was found to be as shown in Table I.

TABLE I.—*Analysis of Dog Biscuit and Horse-Flesh.*

—	Biscuit.	Horse-flesh.	Total in ration.
	Per cent.	Per cent.	Grammes.
Water	15·73	74·94	—
Fat	2·28	2·60	13
Albuminoids	16·62	21·00	99
Carbohydrates	62·89	—	239
Fibre	1·10	—	—
Ash	1·38	1·08	—
Not accounted for.. ..	—	0·38	—
	100·00	100·00	351

For the above analyses the writer is indebted to his colleague, Prof. G. H. Gemmell, F.I.C.

This ration, which the clinical department of this College has found by experience to be suitable for adult dogs weighing about 24 kilos and not getting more than sufficient exercise to keep them in good health, was fixed upon without reference to any former investigation undertaken to determine a satisfactory diet. It is, therefore, particularly interesting to compare it with the rations for dogs suggested by Dechambre.[4] Dechambre published the results of his investigations in 1919, and stated that he considers that maintenance requirements for the dog can be calculated according to the surface law, as is the case with other animals. He published a table setting out the maintenance rations for dogs from 5 to 100 kilos in weight and also gave rations suitable for dogs doing moderate and hard work. For a dog of 27 kilos, such as an Airedale or collie, he allows for maintenance: Protein 55 g., fat 15 g., and carbohydrate 300 g., giving a total of 388 nutritive units reckoned on the formula (total protein + total carbohydrate + total fat × 2·2). The compared rations in grammes, therefore, are as given in Table II.

TABLE II.—*Prepared Ration in Grammes.*

—	Protein.	Fat.	Carbohydrate.	Total nutritive units.
Dechambre ..	55	15	300	388
R. (D.) V. C. ..	99	13	239	367
Difference ..	+44	−2	−61	−21

A comparison of these two rations shows that there is a close similarity in the total nutritive units supplied, but the diet given in this College contains nearly twice as much protein as that recommended by Dechambre and considerably less carbohydrate. The total protein allowed by Dechambre for hard-working dogs of 27 kilos weight is 100 g. As the

380 g. of dog biscuit contains 63 g. of protein, it might be assumed that the biscuits by themselves would constitute a complete food, at least for adult dogs, but experience has shown us that excellent health is maintained when the above quantity of horse-flesh is added to the biscuits. It is also to be assumed that a proportion of the mutton greaves or "cracklings" is not digested by the dog, but at the same time it will serve a useful purpose by supplying bulk to the ration and to some extent take the place of the bones and more or less indigestible skin, some of which is, no doubt, consumed by the dog in its natural state. The albuminoid ratio of Dechambre's ration for the resting dog of 27 kilos is 1 to 6; that of this College, calculated from the chemical analysis, is 1 to 2·7 (the albuminoid ratio of bitch's milk is 1 to 2·2.

It is not suggested that either the ration of Dechambre or that in use here would be suitable for nursing bitches or growing pups. To make the diet complete, bones should be added and the best for this purpose are soft calf bones or the rib bones of lambs, which are easily masticated and digested. Rabbit, game, and poultry bones are to be avoided owing to their splintery nature and the frequency with which they cause serious intestinal lacerations. Though under more natural conditions, such as on farms, dogs possess the capacity to digest these splintery bones without apparently doing them any harm, house-dogs certainly have little power to do so. Some bulky food that is not so readily digested as flesh is an essential constituent of a maintenance ration for the dog, otherwise the excretion of waste products is delayed. Bones, furthermore, are very desirable in order to stiffen and harden the fæces and thus cause evacuation of the anal glands when the rectum is emptied.

In regard to the utilisation of *raw* flesh as part of the normal healthy dog's ration, this would not seem to be necessary. On the other hand, clinical experience has shown us that many cases of eczema in the dog are cured simply by making a complete change in the diet, withholding all carbonaceous food and giving raw flesh only. The potato above all foods seems to give the worst results, and in the opinion of many of us is responsible for a considerable amount of intestinal irritation and cutaneous lesions of an eczematous nature. Excessive feeding with porridge to house-dogs deprived of sufficient exercise also seems to be accountable for some of these troublesome conditions.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE fifteenth annual meeting of the Oxford Ophthalmological Congress took place in the Department of Human Anatomy, Keble College, on July 3rd, 4th, and 5th, and during the greater part of the session was presided over by the Master, Sir Anderson Critchett.

Dr. E. Landolt (Paris) initiated a discussion on the

General Principles of the Treatment of Convergent Concomitant Strabismus.

He said that strabismus meant a vicious relative direction of the two eyes. To secure normal sight the visual lines of the two eyes should be directed simultaneously upon the point which at the moment the person was interested in; the accomplishment of this meant the use of binocular vision. It demanded, therefore, that the image of the object being looked at be formed at the same moment on both foveæ. When binocular vision was not operative in an individual, the cause might be a central one, but in most cases it was due to visual impairment of one of the eyes. The absence of binocular vision was the chief cause of the occurrence of concomitant strabismus. In concomitant strabismus the visual lines crossed either beyond or within the point fixed by one of the eyes. In the former event the squint was divergent (relative or absolute), in the latter it was convergent. When binocular vision was not in operation other influences played a part in determining the relative direction of the two eyes. The first important influence was the direction of the eyes in a state of absolute rest, which was a divergent direction; hence a divergent squint was a passive squint. The second influence was an excessive stimulus to convergence, and therefore this was an active squint, and it might be produced by some special alteration of the nerve centres. It was mostly due, however, to the relationship between convergence and accommodation, an unusual effort to accommodate calling forth excessive convergence. As convergence depended only on the distance of the fixed point, it was the same for all eyes; but accommodation depended also upon the refraction of the eyes. Eyes whose refraction was defective, especially those which were hypermetropic, had to provide a greater amount of accommodation than of convergence, and when binocular vision was not operative the convergence followed the impulse of the accommodation. One eye saw the object distinctly, and the excess of convergence was manifest only in the other eye.

With regard to treatment, the first aim should be to restore binocular vision. This could be done by correcting the optical errors, and particularly the errors of the deviating eye, and in the second place, by isolated visual exercises of this eye and orthoptic exercises of both eyes. Convergent squint required that the spasm of accommodation should be subdued, by such means as the use of mydriatics, the wearing of convex glasses, and giving the eyes rest. If orthoptic treatment failed, surgery would cure the squint—i.e., advancement of the external recti with resection of the extremity of the muscles. He did not advocate surgery to replace the other means, but to complete them.

Dr. E. Thomson devoted his contribution mainly to setting out the measures to be taken for the prevention of the development of the squint. After strabismus had commenced optical correction should be carried out at the earliest possible moment. He reminded members of the cadaveric position of the eyes, their physiological position, and compared these with the position taken up by them in strabismus. He also discussed amblyopia in relation to squint and its incidence and course in children.

The Master, in expressing his high appreciation of both contributions, said he fully recognised the merits of advancement over the former method, of which latter his father was the originator.

Dr. De Schweinitz agreed in the main with Dr. Landolt's contentions. He gave some interesting details of his methods in his Philadelphia clinic.

Mr. T. Harrison Butler said that during the last 18 months he had made muscle recession combined with advancement his sole operation. The failures were of two kinds—failure to correct convergence, and failure to correct divergence. He was referring only to squints of 30° and more. One of the causes of failure after operation was that the powerful internal rectus was continually pulling against the sutures. By detaching the muscle and attaching it to the sclera 4 mm. back the operation was half done, and his results had been much better. He commented on the prevalence of squint among the children of the poor, in contrast with that in the children of the better classes.

Dr. Beatson Hird gave some experiences of his work as ophthalmic surgeon to the City of Birmingham Education Committee. He said the cases of squint

were all seen by him, carefully examined, and kept under periodic examination; 40 per cent. of the children referred to him in this capacity had squint. His aim was to cure refractive errors, and either prevent or cure amblyopia and straighten the optic axes. A printed leaflet of instructions to parents and guardians was distributed, and it had been a considerable help in the work. If the eyes could be got straight he believed many of the cases would fuse well of themselves. He did not hesitate to operate where it was required, and he considered that advancement was by far the best operation. In some cases, those which squinted from a very early age, he considered there was an anatomical peculiarity which accounted for it.

Mr. Ernest Clarke reiterated his views on the subject, calling special attention to the possible ætiology and the necessity of quite early treatment.

Mr. Claude Worth expressed his entire agreement with all the contentions Dr. Landolt had advanced, and gratefully acknowledged his teaching in regard to advancement. Gradually he had himself given up tenotomy. He had never seen the external ocular muscle abnormally strong, but it might be much weaker than usual. He regarded the amblyopia accompanying squint as the most important subject of all. It was in most cases acquired. The occlusion treatment was useless unless it was thorough; and there must be no possible avenue for sight by the side of the bandage, or the effort would be valueless.

Mr. Angus MacGillivray (Dundee) said his own idea of the origin of the amblyopia of squint was, that one eye had not been educated, and he believed that an infant's eyes were blind eyes. In the course of his duties in connexion with recruiting at the time of the war he found a preponderant proportion of blind eyes and squinting eyes among the denizens of towns, and only a small number among those engaged in agricultural occupations.

Dr. Stewart Barrie and Dr. Marion Gilchrist (Glasgow) also spoke.

The Doyne Memorial Lecture was delivered by Mr. Harrison Butler, who spoke on Focal Illumination of the Eye, with special reference to the clinical use of the Gullstrand slit-lamp.

At the Saturday morning session the subject for discussion was

Ophthalmology from a Legal Aspect.

Mr. H. H. Joy, K.C., opened the debate, pointing out the present position of ophthalmic industrial diseases under the Workmen's Compensation Act. He drew attention to a very instructive case in this connexion. An excellent workman with two eyes had an accident to one, the sight of which had been lost some time before. No one but himself had known that only one eye was of use. The accident drew attention to the fact that he was a one-eyed man. He recovered from the injury to the useless eye and was, physically and industrially, as good a man as before. But, from the point of view of the Act, his ability to earn wages—really meaning the opportunity to earn adequate wages—was materially lessened, and he was turned down because he was a one-eyed man. The House of Lords reversed all the decisions of the Courts below, and said he was entitled to compensation because it was in consequence of the accident that he could not thereafter earn wages. Mr. Joy went in detail into the legal aspect of many points in the Act, and discussed the question from the same standpoint as to whether one attack of miner's nystagmus predisposed to a further attack, and whether, therefore, one attack lowered the man's industrial value. A number of opinions quoted showed an inclination to accept that view.

The questions raised were discussed by Mr. Harrison Butler, Dr. C. Harford, Dr. A. Greene, Mr. Bernard Cridland, Col. A. H. Tubby, Mr. R. Coulter, Dr. R. Jaques, Mr. G. H. Pooley, Dr. Park Lewis, Dr. A. S. Percival, Mr. MacGillivray, and Mr. T. L. Llewellyn.

Demonstrations.

During the meetings an adjoining room contained a very full museum of exhibits, and on Friday a number of demonstrations were given. Dr. George Young discussed recent observations on double sclerectomy by trephining without communication with the anterior chamber. Dr. Rayner D. Batten showed: (1) Ophthalmoscopic drawings with the epidiascope illustrating the value of collective drawings shown in cardio-vascular diseases, macular diseases, cerebro-macular disease, congenital diseases, and various unclassified diseases; (2) models of fundus conditions; (3) the hydrophthalmoscope; (4) orbital rigid spectacles with ptosis props; (5) fixation fork for the insertion of sutures in advancements; (6) tension experiments with balloons. Dr. Thomson Henderson showed: (1) sections illustrating various pathological conditions; (2) sections illustrating evolution of ciliary muscle in mammalia.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Register and the Irish Free State.

THERE has been, as far as is known, no development in the situation as regards the Medical Register and the Irish Free State. Some weeks ago the Minister for Local Government heard a full statement from a deputation representing the several licensing bodies, and it was hoped that the Irish Government might without delay move in the direction suggested by Sir Donald MacAlister. Delay in the matter is dangerous. At any moment the Register may be closed to Irish diplomates, and it is much easier to continue an existing system than to arrange a new one. Moreover, to continue the old system temporarily commits neither country as to the future.

National Health Insurance Bill in Ireland.

When the State Government Grant to meet the expenses of medical certification for National Health Insurance purposes was stopped last year, it was necessary for the National Health Insurance Commission to apply funds from various sources towards the expenses of certification. For this purpose legislation was necessary, and the Bill effecting it has now passed through the Dail without much opposition. The present arrangement is purely temporary, and has only been accepted by the medical profession up to August 31st next.

The Medico-Psychological Association.

The Medico-Psychological Association of Great Britain and Ireland held its eighty-third annual meeting at Belfast, July 1st to 5th. About 60 members were present, all parts of the country being well represented. The Government Lunacy Department were represented by Dr. C. H. Bond (England), Sir Arthur Rose, D.S.O., and Dr. H. C. Marr (Scotland), Dr. D. L. Kelly (Irish Free State), Colonel W. R. Dawson and Dr. N. C. Patrick (Northern Ireland). Dr. E. Goodall, the President, took the chair at the preliminary meeting in the Queen's University, at which Sir Frederick Mott was chosen president-elect for the year 1925-26. The following were elected Hon. Members of the Association: Lord Sandhurst, Prof. McDougall (Harvard University), and Colonel Dawson (Chief Medical Officer, Ministry of Home Affairs, Northern Ireland). The following were elected Corresponding Members: Dr. H. Cotton (New Jersey State Hospital) and Prof. Winckler (Utrecht University). Dr. Shaw Bolton was nominated Maudsley Lecturer for 1925. Dr. F. R. Martin read a paper on the Reaction of the Blood to the Ingestion of Protein in the Psychoses, and Dr. Thomas Houston gave a demonstration on the Examination of the Spinal Fluid.

In the afternoon a civic reception to the Association was given in the City Hall by the Lord Mayor of Belfast, Sir W. G. Turner, and this was followed by a luncheon. On reassembling at the Queen's University, a vote of thanks was passed to the officers and council of the Association, and the incoming President, Dr. M. J. Nolan, took the chair. In his inaugural address he dealt with the various schools of thought in psychological medicine; all of which had their contribution to make to practice. These were, he said, elements of truth and value in the different schools; the individual must be studied, and clinical experience must be the chief guide. He emphasised the importance of preventive measures and of early treatment in mental disorders. At the conclusion of the President's address the members inspected the Purdysburn Villa Colony (Belfast Mental Hospital). In the evening a reception was held in the Queen's University, when the guests were received by the Vice-Chancellor, Mr. R. W. Livingstone, M.A., and Mrs. Livingstone.

On Thursday morning, July 3rd, a paper was read by Sir Frederick Mott on the Thyroid Gland in Bodily and Mental Diseases. The comparative iodine content was estimated in 100 thyroid glands obtained from patients dying in general hospitals, in hospitals for consumption, and in asylums. There were no histological changes which could be associated with any particular form of mental disease, nor could one predict the iodine content in these cases. In cases of sudden death, or rapid death from disease, the iodine content was high. It was low on the average in tuberculosis and in chronic dysentery. It was lower than the average in the psychoses and in general paralysis. As nearly all the mental cases died from some chronic bodily disease it was difficult to dissociate the effects of this morbid condition from the effect which the mental state may have had. Attention was called to the thyroid gland being one of the important defences of the body against disease caused by chronic infections using up the thyro-iodine and thus impairing the oxidation processes required for metabolism. Chronic infections might excite or prolong mental disorder in a potentially unstable brain. A paper on Encephalitis Lethargica was then read by Dr. R. Marshall (Belfast), in which the experience gained in Belfast in the last two epidemics was summed up.

The members were entertained to luncheon by the invitation of the Ministry of Home Affairs, Northern Ireland, and in the afternoon an address was given by Dr. Chalmers Watson on Further Reflections on the Rôle of Auto-infection in the Ætiology of Acute and Chronic Mental Disorders. In the evening the annual dinner was held in the Grand Hall of the University, at which about 90 members and guests were present.

On Friday, July 4th, a visit was paid to the County Down Asylum at Downpatrick. Prof. G. M. Robertson read a paper on Is Dementia Præcox a Clinical Entity? in which he discussed the views of Kraepelin and others, but refrained from any dogmatic conclusion. Colonel Dawson read a paper on the Belfast War Hospital and its Work, 1917-19. The asylum was subsequently inspected. After return to town a lecture was given by Prof. T. Walmsley on the Psychology of Primitive Man.

Saturday, July 5th, was devoted to an excursion to the Mourne Mountain District, co. Down.

Report of Inspector of Lunatics, Northern Ireland.

The first report of the Inspector of Lunatics, Northern Ireland, recently published,[1] but covering the years 1921-22, contains the usual statistics and brief records of the state of the asylums in question. There are 4277 insane in six institutions, of which Belfast and Down have up-to-date and well-equipped buildings, whereas the remainder suffer certain structural and other disadvantages. At Armagh there is overcrowding, and adverse comment is made on the dietary, some of the furniture, and the absence of an observation ward. Antrim is also somewhat overfull; the building is in good order, but no regular training is afforded to the attendants and nurses. Londonderry suffers from the antiquated and unsatisfactory nature of the old buildings, and needs an additional medical officer. At Omagh a new water-supply is being sought. There are no references in this report to the general health of the patients in these asylums, or the incidence of such diseases as dysentery, typhoid, and tuberculosis. The conditions here disclosed are characterised by a considerable degree of order, efficiency, and comfort for the patients. The price of this report, consisting of 47 pages only, is 7*s*.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Annual Session of the American Medical Association.

THE seventy-fifth session was held this year in Chicago from June 10th to 13th. There was a record attendance, and the meeting was generally considered to have been a very successful one. The famous Municipal Pier, a huge structure which stretches for nearly a mile into Lake Michigan, provided ample accommodation for the activities of the Association. At the shore end were the offices for registration, information bureau, &c., and beyond this nearly a quarter of a mile devoted to scientific and commercial exhibits from various schools and firms. Beyond this again were large spaces divided off for sectional meetings. On June 9th and 10th diagnostic clinics were held by well-known medical men from all over the country. On the evening of June 10th the opening meeting was held, Dr. Ray Lyman Wilbur, of Stanford University, California, last year's President, being in the chair. The new President, Dr. William A. Pusey, of Chicago, delivered his address on "Some of the Social Problems of Medicine." Dr. Pusey spoke of the tendency of the modern world towards socialisation, and said that the medical profession must form part of the intellectual minority which will check the excesses of this tendency and guide it in the direction of moderation and wisdom. Amongst the distinguished foreign guests present at the Association meeting were: Miss Louisa Martindale, of London; Dr. Leonard Findlay, of Glasgow; Dr. Wills Maclachlan, of Toronto; Prof. Finkelstein, of Berlin; Prof. Petrén, of Lund, Sweden; and Prof. Sendjiak, of Warsaw, Poland. The sectional discussions were too various to enumerate. Among the many interesting addresses was one with demonstrations by Dr. George Dick, of Chicago, on his test for scarlet fever immunity. A feature was a motion-picture theatre at which many topical demonstrations were given.

Of the many ingenious novelties shown at the exhibition perhaps the most remarkable was one by C. T. Gamble, Philadelphia, and Richard Cabot, Boston. This was an electric amplifier stethoscope provided with electrical filters by means of which many scores of people could listen at one time to the same heart or chest, the sounds of which could be amplified more or less as desired. Phonographic records of heart sounds were also exhibited. This device seems to offer great possibilities in the teaching of auscultation, aside from its value as a diagnostic aid.

On the evening of Monday, June 9th, a complimentary dinner was given to Dr. G. H. Simmons on his twenty-fifth anniversary as Editor of the *Journal of the American Medical Association*. Dr. Harvey Cushing was in the chair, and the others who spoke in appreciation of Dr. Simmons's work were: Dr. Frank Billings, Dr. William Mayo, Dr. William D. Jones, Dr. Hubert Work, and Dr. William S. Thayer, the last of whom made the presentation of a portrait by Arvid Nyholm.

---

[1] H.M. Stationery Office, 15, Donegall-square W., Belfast. 7s.

The Work of the A.M.A.—Chicago is the home of the Association. "From a corner in the office of Dr. N. S. Davis, of Chicago, to a six-story plant occupying 100 by 160 feet, and providing ample accommodations for at least the present needs; from a yearly volume of transactions to a weekly publication averaging 144 pages, and a circulation of more than 80,000, with journals for seven medical specialties of importance, a lay journal, and bureaus for all the interests of the physicians—this, in a brief statement, has been the progress of the American Medical Association." Thus runs the first sentence in a booklet published by the Association, describing its work. The organisation represents 90,000 of the 145,000 physicians of the country, and almost 60,000 of them, as Fellows of the Association, take an active interest in its work. The publications edited and printed by the American Medical Association include the *Journal of the American Medical Association*, its Spanish edition, the *American Journal of Diseases of Children*, the *Archives of Internal Medicine*, the *Archives of Surgery*, the *Archives of Neurology and Psychiatry*, the *Archives of Dermatology and Syphilology*, the American Medical Association *Bulletin* and *Hygeia*. The latter is published under the auspices of the Bureau of Health and Public Instruction, the function of which is "to promote in various ways the education of the public along health and medical lines."

One of the most interesting of the departments is that of the Bureau of Investigation directed by Dr. Arthur J. Cramp, which conducts an unceasing campaign against quackery of all sorts. Information of every description, advertisements, pamphlets, &c., used by patent-medicine makers is gathered and filed. Small pamphlets written for the laity are published under therapeutic groups such as "cancer cures," "deafness cures," and "female weakness cures." Any layman making inquiry concerning some quack medicine is furnished with the appropriate pamphlet. "Nostrums and Quackery" is an interesting two-volume compilation of facts about a vast number of patent medicines, and loose-leaf pages of it are sent out to laymen and physicians in answer to letters of inquiry. Many newspapers and magazine editors consult the department concerning the genuineness of solicited advertisements. The information is obtained by original investigations made by the department supplemented by data received from any reputable source outside, including foreign sources such as the report of the Select Committee on Patent Medicines of Great Britain, and the Royal Commission on Secret Drugs, Cures, and Foods of Australia. The whole organisation is a good example of successful centralisation.

Mental Disorder in Immigrants.

A question of greater importance in the United States than elsewhere, but none the less of general interest, is ventilated in a recent issue (Vol. xxxix., No. 17) of the *Public Health Reports of the United States Government*, by Miss M. C. Jarrett. It has been asserted that difficulty of adaptation to new surroundings is a cause of mental disorder in immigrants. From a study of 240 boys of foreign parentage, Miss Jarrett can find no grounds for the belief that the complexity and unfamiliarity of American customs and institutions often cause immigrants to become mentally unbalanced or harassed to the point of committing anti-social acts. The influence of social factors peculiar to immigrants could not be identified as responsible for delinquency or other mental abnormality in any of these cases. The findings are negative, bearing in no way on the general question of mental health in the United States, which is at present receiving much attention. The amount of painstaking social work being carried on may be gathered from the fact that each of the families of some of these cases had been cared for by no less than seven, eight, and in one case 15, different "social agencies."

Public Health Services.

THE HEALTH OF LONDON IN 1923.

Sir William Hamer, medical officer of health and school medical officer to the London County Council, reports that the year 1923 was remarkable for the lowest death-rate and lowest infant mortality-rate ever recorded in London. The Registrar-General estimates the civil population at 4,564,109, and the non-civilian at 6000. The birth-rate was 20·1, the death-rate 11·4, and the infant mortality-rate 61. The death-rates from tuberculosis and cancer were 1·2 and 1·4 respectively. Sir William Hamer discusses the London life-tables since 1841, and shows that in the course of 80 years the Londoner's expectation of life has been extended from 34·6 years to 53·8 years for males, and from 38·3 years to 59·1 years for females. The number of legitimate children born per hundred married women of ages 15 to 45 years has decreased by 29·7 per cent. during this period, and only about 3·2 per cent. of this change is due to the altered age constitution of the married women of child-bearing age.

The year 1923 marks another successful period in dealing with the prevention of *small-pox* in London, only 11 cases with one death having occurred during the year. The wonderful success of this branch of the public health administration is attributed to the close coöperation of the Ministry of Health, the County Council, the Metropolitan Asylums Board, the City Corporation, the Port Authority, the borough councils, and the boards of guardians and sanitary authorities in the area of Greater London. Examples are given of the care taken to search out contacts who may have been infected, and one illustrative case is given of a patient who went about as usual for 24 days after she became infectious before the nature of her case was recognised. The valuable assistance of the Council's experts in diagnosis, Dr. W. McC. Wanklyn and Dr. J. A. H. Brincker, receives due recognition. The notifications of tuberculosis during 1923 were slightly more than twice the deaths in number.

Sir William Hamer discusses the views expressed by Dr. Dublin, the statistician of the Metropolitan Life Insurance Company of New York, as to the influence of *environment* and *heredity* respectively. Dr. Dublin thinks that on the score of geographical variation, the environmentalists have the better of the argument. The sex and age variations also favour the environmentalists, as there is no evidence of a differential heredity endowment among brothers and sisters. Tuberculosis is said to be less fatal among Jews and Italians, but the rates among Jews and Italians respectively vary according to their environment. For an explanation of variation according to economic levels, the eugenists have to rest their case on the superior endowments and vigour of the groups who make up the well-to-do classes of the community as distinguished from the poor. As regards the effect of occupation, the eugenists would need to hold that the persons engaged in various occupations are selected in accordance with their inherited ability to withstand tuberculosis. Finally, Dr. Dublin states that the eugenists lose no opportunity of saying that there has been no improvement in the racial constitution of the people of the U.S.A., but rather a deterioration, and in spite of this the tuberculosis death-rate has fallen by 50 per cent. during the last 20 years. There is good evidence that the population of America is better off. Never before in the history of the country has so favourable a change come over the environment of the people as in the years subsequent to the late war. Sir William Hamer appears to favour his final conclusion that the environmentalists have the best of the argument all through.

The report deals at length with the behaviour of *influenza*, together with the group of diseases which Sir William Hamer associates with it—namely, cerebro-spinal fever, poliomyelitis, and polio-encephalitis and encephalitis lethargica. He suggests that influenza is primarily a disease of the cerebro-spinal nervous system, and that this in part accounts for its protean manifestations, another reason being the lesser stability of the *materies morbi* as compared with organisms like the tubercle bacillus. Major waves of influenza develop about every 15 or 20 years as great pandemic prevalences, and preceding and following each pandemic at intervals of some one, two, or three years come the trailer epidemics. While pandemic influenza especially attacks persons of young adult or adult age, the trailer outbreaks seem to affect rather the young children or old persons who have escaped attack during the pandemic. Sir William Hamer endeavours to account for the disparity between the simple measles curve and the complex influenza curve.

The theory that much of the *typhoid fever* in London has been due to the consumption of immature plaice from the area including the mouth of the Elbe is further discussed, and, in fact, extended to other parts of England, as Sir William Hamer shows that the Humber ports were at one time the source of supply of this class of fish.

The *death-rate from cancer* in London is shown to be slightly higher than that for England and Wales as a whole. During the last 70 years the mortality among males has increased five-fold, while that among females less than two and a half times. The ratio of the male to the female rate, which in 1850–52 was 100 to 195, is now 100 to 83.

During the spring of 1923 publicity was given to a *skin disease caused by wearing furs.* A sample of one of the furs indicated was examined in the Council's laboratory. The furs in question are known as "coney-beaver," and the varieties mainly indicated were those of the lighter shades. The chemical substance which poisons the skin disappears in course of time by volatilisation. The Ministry of Health conferred with the London Fur Traders' Association with regard to the matter, and it is assumed that the measures taken to prevent an occurrence of the mischief have been effective.

In discussing the *venereal diseases schemes,* Sir William Hamer shows that the ratio of attendances to venereal cases is 29 to each new case, a higher ratio than obtains even in those countries where venereal diseases are compulsorily notifiable. The records show that medical practitioners made more use of the facilities for pathological examinations in 1923 than ever before. Sir William Hamer states that most of the suggestions contained in the report of the Trevethin committee have already been embodied in the Council's scheme.

During 1923 Dr. N. D. Bardswell investigated the *after-histories of adult tuberculous persons* in the County of London who received institutional treatment during the year 1918, and his inquiry confirms the usefulness of the sanatorium in the treatment of tuberculosis in its initial stages and its ineffectiveness when the disease is well established. The question is asked: What more can be done to improve the prospects of the moderately advanced case and is a mortality of some 70 per cent. within four years to be accepted as inevitable? The chances of the civilian and the ex-Service man are compared. The ex-Service man has no limit put to his institutional treatment; it may be repeated and prolonged. He is free from financial worries and anxieties about dependents. He has a well-endowed scheme of after-care. One is not surprised to learn, therefore, from the table given that the results of treating ex-Service men are materially better than those of treating comparable cases among the rest of the population.

The death-rate from *puerperal sepsis* per 1000 births was 1·1, about the same as that for England and Wales during the two previous years. The death-rate for other child-birth causes is not given. Nine hundred and five midwives gave notice of their intention to practise within the county, an increase of 76 on last year's figures. Their work is supervised by four women medical inspectors. Midwives attended about 12,000 confinements and sent for medical aid in 17 per cent. of the cases. The births attended by the midwives numbered 45 per cent. of the total births. They were debited with about 30 per cent. of the fatal cases of puerperal fever, and about 60 per cent. of the notified cases of *ophthalmia neonatorum.* Of the 753 cases of this latter disease, 449 occurred in the practice of midwives, of which 420 cases made a complete recovery and there were 12 deaths. The damage done to survivors was as follows: one case of blindness in both eyes, one case of blindness of one eye, two cases of impairment of vision in both, and one of impairment in one eye. In 11 instances the result was not ascertained owing to removal. In addition, two unnotified cases were investigated, one resulting in total blindness and the other in the loss of sight of one eye. Sixty-four cases received in-patient hospital treatment at St. Margaret's Hospital. No information is given as to the damage done to eyesight in the 304 notified cases which did not occur in the practice of midwives. It seems to be of the highest importance on every ground that we should know the complete story from every district in the county with respect to this tragedy of child life.

MENTAL HOSPITALS SERVICE.

Scottish Western Asylums Research Institute.

THE fourteenth annual report of this institute illustrates the results which may be obtained when a group of institutions combine to have their pathological work carried out by a single efficient laboratory, —an arrangement of which there appears to be only one example in England. This example might well be followed by other mental hospitals in which the establishment of individual laboratories is impracticable. Some 2500 investigations have been carried out during the year. Research has been somewhat interrupted by the immense volume of tedious work involved in detecting a number of intermittent typhoid carriers. Dr. W. Whitelaw, the director, discusses the problem of dealing with these carriers after their detection; there is no infallible means of eradicating the infection from these patients, and he very reasonably suggests that all of them throughout Scotland should be gathered together in one institution. "Administration would be easier; isolation would be more efficient; the isolation would be less burdensome to the patients." Among the subjects of original work pursued during the year have been blood-sugar variations in emotional states, calcium metabolism, and the *Bacillus acidophilus* milk treatment. In discussing the treatment of general paralysis, Dr. Whitelaw suggests that if recent methods are to be tested adequately each will have to be applied on as large a scale as possible (as by confining the treatment of this disease in each of several institutions to a single specific method), and the results of this large-scale adoption compared.

Glasgow Royal Asylum.

Several new developments are recorded or foreshadowed in the annual report for 1923. The hospital now has a complete consulting staff of eight members in addition to the resident staff of four medical officers for about 500 patients—five names occur in the list of officers, but both the late second assistant medical officer and his successor are included. Miss Dorothea Robertson has been appointed as "occupational teacher." An "occupational pavilion" has been built, and the results attained already by the systematic teaching of handicrafts to patients who previously "sat listless about the wards" are stated to be excellent. Several recoveries are attributed to the treatment; the wards are quieter, and the general life of the hospital has greatly benefited. The medical superintendent, Dr. D. K. Henderson, discusses at some length the difficulty of finding suitable candidates for the nursing staff. In appealing for "a well-educated, intelligent, and refined type of girl," he points out the advantages of a mental hospital career and the real interest of the work. A new nurses' home is to be built, and it is hoped that its amenities will offer a further inducement to the entry of nurses.

Cumberland and Westmorland Mental Hospital.

In the annual report for 1923 it is recorded that a dental surgeon has been appointed, a step previously recommended by the visiting Commissioners on several occasions. A low recovery-rate, and the small proportion of patients usefully employed, are explained by the admission of many senile and other hopeless cases. "The character of the majority of cases admitted during the last few years shows a marked deterioration." The Commissioner's report suggests extending the practice of giving money allowances to patients on trial, and granting leave on trial to larger numbers. Dr. W. F. Farquharson, the medical superintendent, observes that changes in the female nursing and domestic staff continue to be unduly numerous.

City of Leicester Mental Hospital.

An increase in the number of female patients, and in the ratio of the insane to the general population of Leicester, is recorded in the annual report for 1923. There are now 542 patients, and the hospital is staffed by three medical officers. A visiting dentist has recently been appointed, and appears to have carried out a large amount of work, and an X ray apparatus has been installed. This hospital has three classes of parole—42 patients are allowed outside the hospital unattended, 117 in the grounds, and 147 are allowed to move about the wards and in the ward gardens. In addition 78 are allowed to visit their homes for week-ends. This appears to be a remarkable example of what can be done in allowing freedom to patients when close attention is paid to the possibilities and limitations of each individual case. Dr. J. F. Dixon notes that four escapes (so-called) occurred during the year, all of cases on parole or limited parole, who may more correctly be said to have absented themselves without leave.

Middlesbrough Borough Mental Hospital.

The visiting Commissioner's observations, reprinted in the annual report for 1923, suggest the provision of a more ample stock of clothing and tooth-brushes, greater variety in the diet, and the appointment of a dentist. Outside parole has been allowed to 15 patients, and it is suggested that open doors and limited parole in the grounds might be of similar benefit to a larger number. The hospital contains about 430 patients, and is staffed by two medical officers. The medical superintendent, Dr. J. W. Geddes, states that 58 per cent. of the patients were kept usefully employed, and that the recovery-rate was 41·7 per cent. on the direct admissions.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 5TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 62; scarlet fever, 1267; diphtheria, 619 (as against 692 of the previous week); enteric fever, 138 (as against 181 of the previous week); pneumonia, 657; puerperal fever, 36; cerebro-spinal fever, 10; acute poliomyelitis, 12; encephalitis lethargica, 103 (as against 132 of the previous week); continued fever, 1; dysentery, 6; ophthalmia neonatorum, 132. There were no cases of cholera, plague, acute polio-encephalitis, or typhus fever notified during the week. Of the 62 cases of small-pox, 1 was notified from the County of London (Kensington); 20 from the county of Derby (Derby 7, Chesterfield 11, Chesterfield R.D. 1); 1 from the county of Middlesex (Willesden); 7 from Northumberland (Ashington); 13 from the county of Nottingham (Hucknall 7, Kirkby in Ashfield 3); 4 from the county of Warwick (Coventry); 5 from Yorks, North Riding (Middlesbrough); 6 from Yorks, West Riding (Rotherham 5). Of the cases of encephalitis lethargica, 14 were notified from the County of London (Bermondsey 2, Camberwell 2, Fulham 1, Kensington 1, Paddington 1, St. Marylebone 1, St. Pancras 2, Southwark 1, Stepney 1, Wandsworth 1); 5 from the county of Durham (Sunderland 2); 5 from Bristol; 18 from the county of Lancaster (Liverpool 3, Manchester 8); 3 from Northumberland (Newcastle 2); 4 from the county of Stafford (Burton-upon-Trent 2); 8 from the county of Warwick (Birmingham 5); and 14 from Yorks, West Riding (Sheffield 7).

Deaths.—In the aggregate of great towns, the deaths from influenza fell from 30 (of the previous week) to 21, while deaths from measles fell from 57 (of the previous week) to 36.

Obituary.

SIR SYDNEY RUSSELL-WELLS, M.D., B.Sc., F.R.C.P. LOND., M.P.

WE greatly regret to announce the death on July 14th of Sir Sydney Russell-Wells, Member of Parliament since 1922 for the University of London. Death came with tragic suddenness, for he had been engaged an hour before in his professional duties.

Sydney Russell-Wells was born in London on Sept. 25th, 1869, the son of Benjamin Weston Wells. He was educated privately, his bent for science being early apparent and his first serious study being devoted to chemistry at the Royal College of Science; in 1889 he took his B.Sc. degree at London University from University College, becoming about the same time a Fellow of the Chemical Society. Turning to medicine, Russell-Wells then entered St. George's Hospital, obtaining in succession the Pollock, Treasurer's, and Brackenbury prizes, as well as the coveted William Brown exhibition of £100 tenable for two years. After qualifying M.B. Lond. in 1893, with honours in two subjects, he took a series of house appointments at St. George's, becoming medical registrar, and would no doubt have taken a position there on the honorary staff had not his educational interests already broadened to include much outside the range of clinical medicine. As it was, he became physician to the Seamen's Hospital at Greenwich and to the National Hospital for Diseases of the Heart, Westmoreland-street, as well as lecturer in the London School of Clinical Medicine. In all these capacities his love of detail and lavish expenditure of time were put freely at the use of the post-graduate students from all parts of the world who attended his demonstrations; his clinical directions to patients were those of the practical man and chemist, and many learned to appreciate the adviser who bade them shun the butcher and cherish the baker and greengrocer. His cardiac work included study with Leonard Hill of the influence of resilience of the arterial wall on blood pressure and an elaborate investigation into the cardiac efficiency of 10,000 recruits with alleged circulatory disturbances. A remarkably complete account of a case of intermittent complete heart-block appeared in our columns two years ago.

In the University of London Russell-Wells's interest was lifelong: the University was his hobby, his constant pre-occupation. He stood always as the champion of the external student, and although he came to realise that the degree of medicine differed from that in other faculties mainly because the course of education as well as the examinational results had to be standardised, he was always opposed to any narrow collegiate conception of University life. He saw the need of a faculty of commerce within the University, and having seen it spent years in working out the course of training and wearing down the difficulties urged against it. For long years a senator, with maximal attendances always recorded against his name, Russell-Wells finally obtained the desire of his heart, and from 1919–22, four critical years in its history, presided over the destinies of the University as its Vice-Chancellor. He represented the University on the General Medical Council and on the retirement of Sir Philip Magnus in 1922 succeeded him as representative in the House of Commons. In the House his voice was not often heard apart from his useful contributions in committee to academic and University affairs, but he was pledged to obtain, if possible, substantial modifications in the panel system, and he was strenuously opposed to any attempt to place the insurance medical service under the domination of the approved societies.

Sir Sydney Russell-Wells's services to education were recognised in 1921 by the conferment of a knighthood. He married in 1895 Harriett, third daughter of the late Stephen Smith, who, with one son and two daughters, survives him. Our sympathy goes out to them in their sudden bereavement.

"Audi alteram partem."

MEDICAL EDUCATION: PROPOSED CHANGES.

To the Editor of THE LANCET.

SIR,—A very important movement in connexion with medical education is at present under the consideration of the Senate of the University of London, which, as it must affect clinical as well as intermediate teaching, should not be allowed to pass without the opinions of the teachers of the final subjects being ascertained.

The movement began, we believe, by University College asking to be allowed to hold a special intermediate examination in anatomy, physiology, organic chemistry, and pharmacology for its own students. Apparently the greater number of London teachers in the latter three subjects favour this course, on condition that each teacher shall hold an independent examination, supervised by an external examiner, at his own school, but that there shall be a common paper set by all the teachers as well as by the external examiner or examiners. Doubtless the ideal which these teachers have in their minds is that they will have greater freedom to develop their teaching on their own lines, and will not necessarily be forced to cover the whole range of their subjects with equal care.

The greater number of the teachers of anatomy, on the other hand, while they sympathise with their colleagues' ideals and are willing to support them as far as physiology, organic chemistry, and pharmacology are concerned, have grave doubts whether the system can be applied to anatomy as taught to medical students. Every one of them would prefer, in his own interest, to teach those parts of anatomy which appeal to him most, and, of course, if he did so the examination must be so arranged that his students did not suffer for their lack of knowledge in those parts which he regarded as of secondary importance. They are doubtful, however, if this method, even with a common paper, would best prepare the medical student for his later clinical teaching.

The close association of the surgical and anatomical teachers, which is so much valued by the latter, impresses on them the necessity of giving an even, practical knowledge of the whole human body to their students, as far as the limited time at their disposal allows. A surgeon never knows what anatomical knowledge may not be useful to him, and the same thing may be said, though perhaps in a lesser degree, of the physician and the specialist. It is for this reason that they hope that the question may be regarded as one of sufficient importance to be considered carefully by the Advanced Medical Board, or, better still, by the whole Faculty of Medicine, and that the Senate will not make any sweeping alterations in our methods of teaching and examining in anatomy until the opinion of the whole faculty has been obtained.

The ideals of University College are these which the American universities have already attained. The ideal position of a professor who is free to devote himself to research in his own particular branch and can teach the things which interest him most can be fully appreciated. Has this method, as far as the average student is concerned, produced the best results from a clinical point of view? This is the point upon which our clinical colleagues, who have worked with American physicians and surgeons during the war, can give an opinion. Personally, we hold the London M.B. qualification in great respect and regard it as one of the best triple qualifications in the world. We are quite prepared to advance along the path of progress should we be convinced that a change in our methods is in the best interests of medical education.

We are, Sir, yours faithfully,

F. G. PARSONS,
J. ERNEST FRAZER,
E. BARCLAY-SMITH.

July 10th, 1924.

LEAD POISONING AND CANCER.

To the Editor of THE LANCET.

SIR,—It appears that my attempt—to which you referred in a leading article on June 7th—to secure assistance from statisticians and medical officers of health concerning a *possible* relationship between lead poisoning and immunity to cancer is unlikely to bear fruit in the immediate future for the following reasons:—

First, those who have already expressed their views in print—for example, Prof. E. L. Collis (THE LANCET, June 14th, p. 1239) and Mr. A. Feil (*La Presse Médicale*, June 28th, 1924, p. 1093)—have shown that they do not realise the difficulties of the subject from a statistical point of view. Both Prof. Collis and Mr. Feil take the comparative mortality figures of certain occupations in which lead poisoning may occur, and they assert that these show no evidence of any relationship, such as I have suggested may be possible.

I cannot here discuss all the relevant occupational statistics, so I shall refer only to those of one trade mentioned by them, and also discussed in my address (*Public Health*, June, 1924, p. 217)—namely, that of potters. How, I ask, is it possible to take the cancer mortality figures of all the members of this trade as indicative of the absence of the influence of lead on cancer, when only about 7 per cent. of the workers are exposed to the possibility of lead poisoning, and when to-day only a very small percentage of this 7 per cent. is poisoned with lead? In my address I stated that about 80 per cent. of potters are not exposed to the possibility of lead poisoning, but the more recent publication of Dr. F. Shufflebotham (THE LANCET, July 5th, p. 52) shows that the number is about 93 per cent.!

As I have stated, I do not think it is possible to use with statistical accuracy the present occupational comparative mortality-rates for the purpose I have in view. Nevertheless, to utilise them, as I did, to demonstrate a relationship between deaths from plumbism and deaths from cancer in the particular trades in which lead poisoning is most common, is justifiable as a preliminary procedure, provided the decennial increase is taken into account, and the age-periods between 25 and 65 years alone are considered. In regard to the last condition, it may be stated that the death-rate from cancer is greater after the age of 70 years in the ratio of more than 2 to 1—that is, after a majority of persons have ceased to work. In a table, which I repeat here, I show that in the only trade in which fatal lead poisoning increased during the decennial period considered the cancer death-rate decreased; and that in the two other trades a decrease in the number of deaths from plumbism was accompanied by an increase, above the normal, of deaths from cancer.

Comparative Mortality-rate per 100.000 Population at Ages 25–65 Years.

—		1900–1902.	1910–1912.	Percentage increase or decrease.
All males ..	Cancer ..	68	78	+15
	Plumbism .	1	1	0
File makers..	Cancer ..	57	78	+37
	Plumbism .	56	10	−82
Lead manufacture ..	Cancer ..	81	80	−1
	Plumbism .	102	123	+21
Plumbers, painters, and glaziers ..	Cancer ..	73	87	+19
	Plumbism .	23	20	−13

I do not assume statistical accuracy for these figures, but at least they are suggestive.

Secondly, the following conditions for statistical investigations must be observed: (*a*) Inevitability of lead poisoning; (*b*) existence of lead poisoning; (*c*) coexistence of one of these conditions with the

Cumberland and Westmorland Mental Hospital.

In the annual report for 1923 it is recorded that a dental surgeon has been appointed, a step previously recommended by the visiting Commissioners on several occasions. A low recovery-rate, and the small proportion of patients usefully employed, are explained by the admission of many senile and other hopeless cases. "The character of the majority of cases admitted during the last few years shows a marked deterioration." The Commissioner's report suggests extending the practice of giving money allowances to patients on trial, and granting leave on trial to larger numbers. Dr. W. F. Farquharson, the medical superintendent, observes that changes in the female nursing and domestic staff continue to be unduly numerous.

City of Leicester Mental Hospital.

An increase in the number of female patients, and in the ratio of the insane to the general population of Leicester, is recorded in the annual report for 1923. There are now 542 patients, and the hospital is staffed by three medical officers. A visiting dentist has recently been appointed, and appears to have carried out a large amount of work, and an X ray apparatus has been installed. This hospital has three classes of parole—42 patients are allowed outside the hospital unattended, 117 in the grounds, and 147 are allowed to move about the wards and in the ward gardens. In addition 78 are allowed to visit their homes for week-ends. This appears to be a remarkable example of what can be done in allowing freedom to patients when close attention is paid to the possibilities and limitations of each individual case. Dr. J. F. Dixon notes that four escapes (so-called) occurred during the year, all of cases on parole or limited parole, who may more correctly be said to have absented themselves without leave.

Middlesbrough Borough Mental Hospital.

The visiting Commissioner's observations, reprinted in the annual report for 1923, suggest the provision of a more ample stock of clothing and tooth-brushes, greater variety in the diet, and the appointment of a dentist. Outside parole has been allowed to 15 patients, and it is suggested that open doors and limited parole in the grounds might be of similar benefit to a larger number. The hospital contains about 430 patients, and is staffed by two medical officers. The medical superintendent, Dr. J. W. Geddes, states that 58 per cent. of the patients were kept usefully employed, and that the recovery-rate was 41·7 per cent. on the direct admissions.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 5TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 62; scarlet fever, 1267; diphtheria, 619 (as against 692 of the previous week); enteric fever, 138 (as against 181 of the previous week); pneumonia, 657; puerperal fever, 36; cerebro-spinal fever, 10; acute poliomyelitis, 12; encephalitis lethargica, 103 (as against 132 of the previous week); continued fever, 1; dysentery, 6; ophthalmia neonatorum, 132. There were no cases of cholera, plague, acute polio-encephalitis, or typhus fever notified during the week. Of the 62 cases of small-pox, 1 was notified from the County of London (Kensington); 20 from the county of Derby (Derby 7, Chesterfield 11, Chesterfield R.D. 1); 1 from the county of Middlesex (Willesden); 7 from Northumberland (Ashington); 13 from the county of Nottingham (Hucknall 7, Kirkby in Ashfield 3); 4 from the county of Warwick (Coventry); 5 from Yorks, North Riding (Middlesbrough); 6 from Yorks, West Riding (Rotherham 5). Of the cases of encephalitis lethargica, 14 were notified from the County of London (Bermondsey 2, Camberwell 2, Fulham 1, Kensington 1, Paddington 1, St. Marylebone 1, St. Pancras 2, Southwark 1, Stepney 1, Wandsworth 1); 5 from the county of Durham (Sunderland 2); 5 from Bristol; 18 from the county of Lancaster (Liverpool 3, Manchester 8); 3 from Northumberland (Newcastle 2); 4 from the county of Stafford (Burton-upon-Trent 2); 8 from the county of Warwick (Birmingham 5); and 14 from Yorks, West Riding (Sheffield 7).

Deaths.—In the aggregate of great towns, the deaths from influenza fell from 30 (of the previous week) to 21, while deaths from measles fell from 57 (of the previous week) to 36.

Obituary.

SIR SYDNEY RUSSELL-WELLS, M.D., B.Sc., F.R.C.P. LOND., M.P.

WE greatly regret to announce the death on July 14th of Sir Sydney Russell-Wells, Member of Parliament since 1922 for the University of London. Death came with tragic suddenness, for he had been engaged an hour before in his professional duties.

Sydney Russell-Wells was born in London on Sept. 25th, 1869, the son of Benjamin Weston Wells. He was educated privately, his bent for science being early apparent and his first serious study being devoted to chemistry at the Royal College of Science; in 1889 he took his B.Sc. degree at London University from University College, becoming about the same time a Fellow of the Chemical Society. Turning to medicine, Russell-Wells then entered St. George's Hospital, obtaining in succession the Pollock, Treasurer's, and Brackenbury prizes, as well as the coveted William Brown exhibition of £100 tenable for two years. After qualifying M.B. Lond. in 1893, with honours in two subjects, he took a series of house appointments at St. George's, becoming medical registrar, and would no doubt have taken a position there on the honorary staff had not his educational interests already broadened to include much outside the range of clinical medicine. As it was, he became physician to the Seamen's Hospital at Greenwich and to the National Hospital for Diseases of the Heart, Westmoreland-street, as well as lecturer in the London School of Clinical Medicine. In all these capacities his love of detail and lavish expenditure of time were put freely at the use of the post-graduate students from all parts of the world who attended his demonstrations; his clinical directions to patients were those of the practical man and chemist, and many learned to appreciate the adviser who bade them shun the butcher and cherish the baker and greengrocer. His cardiac work included study with Leonard Hill of the influence of resilience of the arterial wall on blood pressure and an elaborate investigation into the cardiac efficiency of 10,000 recruits with alleged circulatory disturbances. A remarkably complete account of a case of intermittent complete heart-block appeared in our columns two years ago.

In the University of London Russell-Wells's interest was lifelong: the University was his hobby, his constant pre-occupation. He stood always as the champion of the external student, and although he came to realise that the degree of medicine differed from that in other faculties mainly because the course of education as well as the examinational results had to be standardised, he was always opposed to any narrow collegiate conception of University life. He saw the need of a faculty of commerce within the University, and having seen it spent years in working out the course of training and wearing down the difficulties urged against it. For long years a senator, with maximal attendances always recorded against his name, Russell-Wells finally obtained the desire of his heart, and from 1919–22, four critical years in its history, presided over the destinies of the University as its Vice-Chancellor. He represented the University on the General Medical Council and on the retirement of Sir Philip Magnus in 1922 succeeded him as representative in the House of Commons. In the House his voice was not often heard apart from his useful contributions in committee to academic and University affairs, but he was pledged to obtain, if possible, substantial modifications in the panel system, and he was strenuously opposed to any attempt to place the insurance medical service under the domination of the approved societies.

Sir Sydney Russell-Wells's services to education were recognised in 1921 by the conferment of a knighthood. He married in 1895 Harriett, third daughter of the late Stephen Smith, who, with one son and two daughters, survives him. Our sympathy goes out to them in their sudden bereavement.

I have no objection to severe criticism. On the contrary, I like it. It is beneficial to a writer. But I think that your reviewer is hardly entitled to condemn my volume wholesale and accuse me repeatedly of producing "statistical fallacies," a polite way of saying something grossly impolite. I would, therefore, ask your reviewer either to substantiate his accusation or to withdraw it. He owes an explanation rather to your readers than to me, and I trust that in the interests of fair play you will print my letter and give your reviewer space for a reply.

I am, Sir, yours very truly,

July 12th, 1924. J. ELLIS BARKER.

*** Cancer is a disease which has no specific symptoms and no obvious signs, except when a tumour happens to be on the surface of the body. It can be diagnosed with certainty only by microscopic examination either after operation or after death. It increases rapidly with increasing age, and rarely affects young people. In order to make a statistical comparison between the incidence of cancer in different communities it is necessary to know: (1) The size of the population in the community; (2) its age-constitution; (3) the facilities for medical examination and readiness on the part of the community to avail themselves of medical help; (4) the facilities for post-mortem examination, since even with the best medical service available about 30 per cent. of cases of cancer are only recognised at the post-mortem examination. In uncivilised races our knowledge of (1) and (2) is nil, facilities for (4) are nil, and facilities for (3) are much less than in a civilised community. Even between different civilised communities a useful comparison of cancer statistics is impossible unless facilities for (3) and (4) are about equal. As an example of the author's arguments we might refer to p. 27, where, in order to prove that "cancer is increasing in the most startling manner," he compares the death-rate from cancer in England in 1838–42 with that in 1921, and points out that it has increased sevenfold. In 1838–42 Virchow had not lived and pathology as a science did not exist. —ED. L.

CENTENARY OF UNIVERSITY COLLEGE, LONDON.

To the Editor of THE LANCET.

SIR,—The hundredth anniversary of the foundation of University College, London, will be celebrated in 1926. Materials (records, reminiscences, pictures, photographs, &c.) are being collected with a view to the production of a history of the College as a part of the centenary celebrations. The volume will include a chapter on the contribution of the College to medical education and research. Members and friends of the College are invited to send such materials as they can contribute to my care for the use of the historian, who will shortly be appointed. All documents will be carefully marked with the owner's names and will, in due course, be returned unless the owners desire to present them for the College archives. Communications and parcels (marked "Centenary") should be sent to me at the College.

I am, Sir, yours faithfully,

GREGORY FOSTER,
Fellow and Provost.

University College, London, July, 1924.

SCHOOL CLOSURE FOR INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—The leading article in your issue of May 3rd hits off precisely the views accepted at our public school. Our practice is to let the parents know, while we advise them to allow the boys to remain. Should they remove them, they do so at their own risk. I recall that at the time of King George's coronation, when a week's holiday was granted at most public schools, our school was in the midst of an epidemic of measles. We advised parents that travel was a risk to boys who had not had measles, and we expressed willingness to keep unprotected boys, of whom a few stayed. Although every boy who had not had measles was carefully examined before leaving, at least three developed the disease on their long journey home. One of these nearly died and was never fit for school again. In the influenza outbreak of 1918 all parents were urged not to take their boys home until after the epidemic was over. Only on special request, and with a signed statement that all risks were accepted, was any boy allowed to leave, and only a few went. One who lived in Edinburgh developed influenza on the journey and died of pneumonia. This was the only death in connexion with the school. 410 cases were nursed here, all of which recovered and were able to go home at Christmas. Every house was converted into a hospital; directly a boy complained he was put to bed and examined. The results of these two epidemics would certainly have removed any doubts I may previously have cherished. Further, in the summer of 1922, when we had 127 cases of measles, the school kept going, and every case did well. Of course, a school should have sanatorium accommodation adequate to its numbers, and it is notorious that preparatory and boarding schools are often short of such accommodation, when there is nothing for it but to send the unfortunate children home. Paragraph XXIII. of the Code of Rules drawn up by the Society of Medical Officers of Schools is clear, and I agree with it. As for the elementary schools, the unfortunate medical officer is pretty well bound to close the school when attendances drop, to save financial loss through stoppage of grants.

You will have done good if you wake up public opinion against a practice which results in the school authorities taking fees and doing little or nothing in return except avail themselves of the opportunity to shut down on the outbreak of infectious disease. There is the risk of spreading the particular infection at home.

I am, Sir, yours faithfully,

MEDICAL OFFICER TO A PUBLIC SCHOOL.

July 15th, 1924.

A CHEMICAL ENCYCLOPÆDIA.

To the Editor of THE LANCET.

SIR,—I feel bound to make a protest against the scandalous way in which my Chemical Encyclopædia (third edition) has been dealt with by your reviewer in THE LANCET of July 5th, and would call your attention to the reviews given in the *Chemical Trade Journal* of May 9th and the *Pharmaceutical Journal* of May 17th, both of which are enclosed herewith, and which will show you that the book covers practically the whole areas of chemical science, materials, theory, terms, and its application to chemical industries and chemical engineering. No attempt has ever been made before to produce an encyclopædia covering so much ground and (according to the general consensus of expressed opinions) the task has not been unsuccessfully accomplished; yet your reviewer dismisses such laboriously achieved work with a somewhat contemptuous reference of eight lines.

In conclusion, I would refer you to THE LANCET review of the second edition (which was a work of a much smaller and less comprehensive character) given in your issue of Feb. 18th, 1922, and I hope you will see some way of doing more justice to me in the matter.

I am, Sir, yours faithfully,

Weybridge, July 7th, 1924. C. T. KINGZETT.

*** The works of direct professional interest are now very numerous and our space is chiefly employed in the attempt to notice them fully and promptly. There is nothing contemptuous whatever in a brief review, at least in intention, especially where the work in question is in its third edition.—ED. L.

onset of cancer. The evidence of Mr. T. W. Stuart and Mr. F. A. Johnson, given in my address, seems to prove, as conclusively as personal statements can prove anything, that men who inevitably inhale lead during their work are immune to malignant disease.

Meanwhile, I take up no position in the matter other than that of an inquirer. I have put forward what seems to be suggestive, but not conclusive evidence. I now await the answer. It may be ten years before this can be given. Before that time has elapsed we shall probably have the answer to the whole question. We ourselves may be using some other preparation than lead, which at present is the best agent we can find for destruction of the chorionic epithelium, and, therefore, as we believe, of malignant cells.

I am, Sir, yours faithfully,

Liverpool, July 10th, 1924. W. BLAIR BELL.

EMETINE IN THE TREATMENT OF ALCOHOL AND MORPHINE HABITS.

To the Editor of THE LANCET.

SIR,—In "Hormone Therapy"[1] I advocated hypodermic injections of emetine hydrochloride for alcoholism, and considered it specific for the craving. At that time only 18 to 20 cases had been reported, but since then over 100 cases have been under treatment so that a fuller experience is now available. This added experience has been shared by others. In "Minor Maladies" Dr. Leonard Williams reports success with emetine hydrochloride, but is not prepared to admit its specificity. There are 3 per cent. to 5 per cent. of alcoholic cases who do not respond to the usual injection of one-third of a grain. It is found that by reducing the dose to one-sixth or one-ninth of a grain these patients begin to recover and to exhibit the same improvement as do normal cases with the full dose.

In the treatment of alcoholism the usual routine is to give an injection of one-third of a grain of emetine hydrochlor. every second day for three doses. In some cases it may be found advisable to give one every day for three doses. After the first three the interval between succeeding doses is lengthened by a day. Thus injections are usually given on days—1, 3, 5, 8, 12, 17, 23, 30. This usually constitutes a course, although an injection once a week may be given for some time afterwards if thought advisable. With the emetine injections I give the following mixture :—

℞ Sod. glycerophos... .. .. ʒii.
Mist. pepsin co. c. bism. .. ℥iss.
Hormonax .. .. .. ℥vi.
Aq. menth. pip. ad .. .. ℥xii.
Sig. ℥ss. ex aq. four times a day.

The reason for the increasing interval between the injections is that emetine is cumulative in action. Alcohol is discontinued as soon as possible, for each dose of it weakens the action of the emetine. Four ounces of alcohol may be given for the first 24 hours and the amount reduced by an ounce each day. There may be some elasticity about this rule, but alcohol should be discontinued as early as possible.

The effect on the nervous system is very marked. A man very soon realises that he is getting a grip of himself and the improvement in his personal appearance corresponds. When a case has gone on to delirium tremens there is no better treatment than emetine. The result of each injection should be watched (they should be given daily for several days), and reduced in strength when the symptoms suggest the advisability of this. Also a suitable quantity of bromide may be added to the mixture.

When "Hormone Therapy" was published I had had no experience with emetine except in alcoholic cases, but I suggested its use in morphine and other drug addictions. In the *Medical Press* of Nov. 29th, 1922, Margaret Vivian reported good results in three cases of morphine habit treated with emetine. Since then I have had two cases, both very successful.

R. P., aged 61, medical practitioner, habit of ten years' duration, a debilitated, decrepit man for his years, weight under 100 lb. Was taking 5 to 6 gr. a day. Had tried many treatments without success. Result was that all morphine was discontinued in 14 days, and three weeks later when he was told that he had not had any for three weeks he could scarcely believe it. He had not known when the drug had been withdrawn.

I. A., aged 50, medical practitioner, a very long-standing case of drug addiction. A heavy lethargic man who was taking various amounts up to and over 20 gr. a day. The drug in his case was wholly discontinued in 12 days, and a fortnight later he was told that he had had none all that time. He had not known when morphine had been discontinued.

The change in the general condition of both men was very marked. The first recovered vigour and put on 20 lb. weight, while the second lost his besotted appearance and appeared perfectly normal. The treatment in both was exactly as for alcohol. In each case it was resolved to begin with three grains a day. Two bottles were prepared : (*a*) A four-ounce mixture containing *half a grain* of morphine hydrochloride *in every 20 minims*, and (*b*) an eight-ounce mixture with sufficient quin. sulphat. in it to simulate the taste of (*a*). Six doses of 20 minims each were given every day from (*a*) and the bottle filled up from (*b*). At the end of 12 to 14 days there was so little morphine left in (*a*) that it was put aside and (*b*) alone was used for the remainder of the time.

Some cases may succeed without being put under control, but for uniform results the alcoholic cases should be detained for at least a fortnight and the morphine cases for not less than four weeks. The habits of years are not easily eradicated even although the craving may have disappeared. In such cases, both with alcohol and morphine, there are many who once restored never relapse, but many of the periodical type return for treatment from time to time. The treatment is just as successful in recurrences. Many learn to come at the very onset, and a few injections prevent the usual results.

Shortly, we have in emetine a treatment which destroys the craving for alcohol and morphine, which builds up the patient's whole nervous system, and thus materially aids in the treatment of such drug habits.

I am, Sir, yours faithfully,

D. MONTGOMERIE PATON, L.R.C.P. & S. Edin.

Heidelberg, Victoria, April 11th, 1924.

CANCER: HOW IT IS CAUSED, HOW IT CAN BE PREVENTED.

To the Editor of THE LANCET.

SIR,—In your issue of to-day you print a very brief review of my book on cancer. The reviewer states that my explanation of the causation of cancer is "not new," that I am "very ill-informed on the subject," and he accuses me twice of producing "statistical fallacies." I suppose I must have produced an absolutely rotten book.

Curiously enough, your reviewer's condemnation stands alone. I have received so far approximately 30 reviews of a column or more, printed in the *Times* and other leading papers, and practically unanimously the writers give to my volume the highest praise which can be given to it. It has been a marvellous reception, and the 30 odd eulogies were apparently all written by eminent medical men, some of whom appended their signatures. I would also draw your attention to the fact that Sir Arbuthnot Lane has stated in his introduction the opinion that my book might be considered "easily the most important practical work on cancer existing in English or in any other language." In addition to these printed testimonies, I have received private letters full of praise and of fervent good wishes from a great many leading medical men, and among these letters are two signed by great specialists on cancer.

---

[1] Baillière, Tindall and Cox. 1922.

I have no objection to severe criticism. On the contrary, I like it. It is beneficial to a writer. But I *think that your reviewer is hardly entitled to condemn* my volume wholesale and accuse me repeatedly of producing "statistical fallacies," a polite way of saying something grossly impolite. I would, therefore, ask your reviewer either to substantiate his accusation or to withdraw it. He owes an explanation rather to your readers than to me, and I trust that in the interests of fair play you will print my letter and give your reviewer space for a reply.

I am, Sir, yours very truly,

Two bottles were prepared : (*a*) A four-ounce mixture containing *half a grain* of morphine hydrochloride *in every 20 minims*, and (*b*) an eight-ounce mixture with sufficient quin. sulphat. in it to simulate the taste of (*a*). Six doses of 20 minims each were given every day from (*a*) and the bottle filled up from (*b*). At the end of 12 to 14 days there was so little morphine left in (*a*) that it was put aside and (*b*) alone was used for the remainder of the time.

Some cases may succeed without being put under control, but for uniform results the alcoholic cases should be detained for at least a fortnight and the morphine cases for not less than four weeks. The habits of years are not easily eradicated even although the craving may have disappeared. In such cases, both with alcohol and morphine, there are many who once restored never relapse, but many of the periodical type return for treatment from time to time. The treatment is just as successful in recurrences. Many learn to come at the very onset, and a few injections prevent the usual results.

Shortly, we have in emetine a treatment which destroys the craving for alcohol and morphine, which builds up the patient's whole nervous system, and thus materially aids in the treatment of such drug habits.

I am, Sir, yours faithfully,

D. MONTGOMERIE PATON, L.R.C.P. & S. Edin.

Heidelberg, Victoria, April 11th, 1924.

CANCER: HOW IT IS CAUSED, HOW IT CAN BE PREVENTED.

To the Editor of THE LANCET.

SIR,—In your issue of to-day you print a very brief review of my book on cancer. The reviewer states that my explanation of the causation of cancer is "not new," that I am "very ill-informed on the subject," and he accuses me twice of producing "statistical fallacies." I suppose I must have produced an absolutely rotten book.

Curiously enough, your reviewer's condemnation stands alone. I have received so far approximately 30 reviews of a column or more, printed in the *Times* and other leading papers, and practically unanimously the writers give to my volume the highest praise which can be given to it. It has been a marvellous reception, and the 30 odd eulogies were apparently all written by eminent medical men, some of whom appended their signatures. I would also draw your attention to the fact that Sir Arbuthnot Lane has stated in his introduction the opinion that my book might be considered "easily the most important practical work on cancer existing in English or in any other language." In addition to these printed testimonies, I have received private letters full of praise and of fervent good wishes from a great many leading medical men, and among these letters are two signed by great specialists on cancer.

---

[1] Baillière, Tindall and Cox. 1922.

I have no objection to severe criticism. On the contrary, I like it. It is beneficial to a writer. But I think that your reviewer is hardly entitled to condemn my volume wholesale and accuse me repeatedly of producing "statistical fallacies," a polite way of saying something grossly impolite. I would, therefore, ask your reviewer either to substantiate his accusation or to withdraw it. He owes an explanation rather to your readers than to me, and I trust that in the interests of fair play you will print my letter and give your reviewer space for a reply.

I am, Sir, yours very truly,

July 12th, 1924. J. ELLIS BARKER.

*** Cancer is a disease which has no specific symptoms and no obvious signs, except when a tumour happens to be on the surface of the body. It can be diagnosed with certainty only by microscopic examination either after operation or after death. It increases rapidly with increasing age, and rarely affects young people. In order to make a statistical comparison between the incidence of cancer in different communities it is necessary to know: (1) The size of the population in the community; (2) its age-constitution; (3) the facilities for medical examination and readiness on the part of the community to avail themselves of medical help; (4) the facilities for post-mortem examination, since even with the best medical service available about 30 per cent. of cases of cancer are only recognised at the post-mortem examination. In uncivilised races our knowledge of (1) and (2) is nil, facilities for (4) are nil, and facilities for (3) are much less than in a civilised community. Even between different civilised communities a useful comparison of cancer statistics is impossible unless facilities for (3) and (4) are about equal. As an example of the author's arguments we might refer to p. 27, where, in order to prove that "cancer is increasing in the most startling manner," he compares the death-rate from cancer in England in 1838–42 with that in 1921, and points out that it has increased sevenfold. In 1838–42 Virchow had not lived and pathology as a science did not exist. —ED. L.

CENTENARY OF UNIVERSITY COLLEGE, LONDON.

To the Editor of THE LANCET.

SIR,—The hundredth anniversary of the foundation of University College, London, will be celebrated in 1926. Materials (records, reminiscences, pictures, photographs, &c.) are being collected with a view to the production of a history of the College as a part of the centenary celebrations. The volume will include a chapter on the contribution of the College to medical education and research. Members and friends of the College are invited to send such materials as they can *contribute* to my care for the use of the historian, who will shortly be appointed. All documents will be carefully marked with the owner's names and will, in due course, be returned unless the owners desire to present them for the College archives. Communications and parcels (marked "Centenary") should be sent to me at the College.

I am, Sir, yours faithfully,

GREGORY FOSTER,
Fellow and Provost.

University College, London, July, 1924.

SCHOOL CLOSURE FOR INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—The leading article in your issue of May 3rd hits off precisely the views accepted at our public school. Our practice is to let the parents know, while we advise them to allow the boys to remain. Should they remove them, they do so at their own risk. I recall that at the time of King George's coronation, when a week's holiday was granted at most public schools, our school was in the midst of an epidemic of measles. We advised parents that travel was a risk to boys who had not had measles, and we expressed willingness to keep unprotected boys, of whom a few stayed. Although every boy who had not had measles was carefully examined before leaving, at least three developed the disease on their long journey home. One of these nearly died and was never fit for school again. In the influenza outbreak of 1918 all parents were urged not to take their boys home until after the epidemic was over. Only on special request, and with a signed statement that all risks were accepted, was any boy allowed to leave, and only a few went. One who lived in Edinburgh developed influenza on the journey and died of pneumonia. This was the only death in connexion with the school. 410 cases were nursed here, all of which recovered and were able to go home at Christmas. Every house was converted into a hospital; directly a boy complained he was put to bed and examined. The results of these two epidemics would certainly have removed any doubts I may previously have cherished. Further, in the summer of 1922, when we had 127 cases of measles, the school kept going, and every case did well. Of course, a school should have sanatorium accommodation adequate to its numbers, and it is notorious that preparatory and boarding schools are often short of such accommodation, when there is nothing for it but to send the unfortunate children home. Paragraph XXIII. of the Code of Rules drawn up by the Society of Medical Officers of Schools is clear, and I agree with it. As for the elementary schools, the unfortunate medical officer is pretty well bound to close the school when attendances drop, to save financial loss through stoppage of grants.

You will have done good if you wake up public opinion against a practice which results in the school authorities taking fees and doing little or nothing in return except avail themselves of the opportunity to shut down on the outbreak of infectious disease. There is the risk of spreading the particular infection at home.

I am, Sir, yours faithfully,

MEDICAL OFFICER TO A PUBLIC SCHOOL.

July 15th, 1924.

A CHEMICAL ENCYCLOPÆDIA.

To the Editor of THE LANCET.

SIR,—I feel bound to make a protest against the scandalous way in which my Chemical Encyclopædia (third edition) has been dealt with by your reviewer in THE LANCET of July 5th, and would call your attention to the reviews given in the *Chemical Trade Journal* of May 9th and the *Pharmaceutical Journal* of May 17th, both of which are enclosed herewith, and which will show you that the book covers practically the whole areas of chemical science, materials, theory, terms, and its application to chemical industries and chemical engineering. No attempt has ever been made before to produce an encyclopædia covering so much ground and (according to the general consensus of expressed opinions) the task has not been unsuccessfully accomplished; yet your reviewer dismisses such laboriously achieved work with a somewhat contemptuous reference of eight lines.

In conclusion, I would refer you to THE LANCET review of the second edition (which was a work of a much smaller and less comprehensive character) given in your issue of Feb. 18th, 1922, and I hope you will see some way of doing more justice to me in the matter.

I am, Sir, yours faithfully,

Weybridge, July 7th, 1924. C. T. KINGZETT.

*** The works of direct professional interest are now very numerous and our space is chiefly employed in the attempt to notice them fully and promptly. There is nothing contemptuous whatever in a brief review, at least in intention, especially where the work in question is in its third edition.—ED. L.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health in Scotland.

SPEAKING in the House of Commons on July 3rd on a vote of £1,897,832 to complete the sum necessary to defray the salaries and expenses of the Scottish Board of Health, Mr. JAMES STEWART (Parliamentary Under-Secretary of Health for Scotland) reported that the year 1923, measured by the death-rate, was the healthiest year on record. The general death-rate fell to the low figure of 12·9 per 1000 of the population, the lowest previous rate being 13·6 per 1000 in 1921. Realising the importance of the health services of the country, one of the first actions of the Government had been to remove the embargo placed on the development of those services by the late Government, and the local authorities had responded to their action by submitting for the approval of the Board of Health developments and extensions of schemes which had been hung up owing to the embargo. It must be their aim to use to the fullest extent the resources of medical and sanitary science in diminishing the heavy burden of sickness, a large part of which was capable of being treated on preventive lines. In addition to measures for better housing, it was necessary to prevent the pollution of the atmosphere by smoke. He hoped a Bill dealing with smoke abatement in Scotland would be introduced at an early date.

There was increasing evidence that the shortage of hospital accommodation in Scotland was a serious gap in the community's protective organisation against disease. Some steps must be taken to repair it by securing closer coöperation between the voluntary hospitals and the Poor-law and public health hospitals. Impressed with the importance of the subject, the Board of Health had recently appointed a Departmental Committee, presided over by Lord Mackenzie, " to inquire into and to report upon the extent and nature of the inadequacy of the present hospital and ancillary services in Scotland, and to make recommendations for the development and maintenance of these services to meet the needs of the community."

Mortality from Tuberculosis.

Slowly but steadily the mortality from tuberculosis was lessening. In 1914 the deaths from that disease numbered 7696, whereas in 1923 they had fallen to 5786. In 1894 the death-rate in Scotland from pulmonary tuberculosis was 172 per 100,000 of the population; in 1914 the corresponding rate had fallen to 104, and in 1923 it had been still further reduced to 81. In respect of pulmonary tuberculosis Scotland had now a lower death-rate than England and Ireland. In the same period of 30 years the death-rate from non-pulmonary tuberculosis had fallen from 63 per 100,000 of the population in 1894 to 58 in 1914 and 36 in 1923. Notwithstanding the fact that the death-rate from this form of the disease showed a fall of 38 per cent. since 1914, Scotland occupied the unenviable position of having the highest death-rate of any of the three countries from non-pulmonary tuberculosis. But he had great hopes that the efforts of the local authorities would soon produce beneficial results which would be reflected in a still further substantial diminution of the death-rate.

There had been a substantial addition to the number of sanatorium and hospital beds reserved for the treatment of this disease. In 1918, at the close of the war, the number of such beds was 2590; to-day there were 3953 beds, and when the extensions, particularly in Glasgow, were finished they would have over 4800 beds reserved for the treatment of this disease. Local authorities must be encouraged to carry on and extend their activities where necessary. The local authorities would now receive in grant 50 per cent. of all reasonable expenditure in connexion with the treatment of this disease.

Maternity and Child Welfare.

With regard to maternity and child welfare in 1923, the deaths under 1 year numbered 80,825, equivalent to a death-rate of 78·9 per 1000 births. This was the lowest infantile death-rate ever recorded for Scotland. The deaths for 1923 over 1 year and under 5 years numbered 4926, equivalent to 12·3 per 1000 children within those ages. Here, again, the death-rate was the lowest on record for Scotland. In 1915 14,441 infants died under 1 year, equivalent to a death-rate of 126·5 per 1000 births, and 9120 children from 1 year to 5 years died, equal to a death-rate of 22·5 per 1000 children of those ages. Unfortunately, while the process of reducing the mortality among infants had been continuous, it was far from being a steady progress. In the first quarter of 1924 the infantile mortality-rate in Scotland rose to 132 per 1000 births, against 98 for the corresponding quarter in 1923. Only in June did the death-rate among children return to a less alarming level. In large measure this high mortality was due to a widespread epidemic of measles and whooping-cough, and to other diseases such as pneumonia that followed these infections. The Scottish Board of Health had issued a circular to local authorities with regard to the further control and treatment of these epidemic diseases, and a special sum of £10,000 had been set aside as part of the maternity and child welfare grant which would be distributed in a manner designed to encourage local authorities to institute further measures for the preservation of child life from the ravages of these very deadly diseases.

A special inquiry in 1908 revealed the following general facts regarding measles, which, like tuberculosis, was a poverty disease. The death-rate from measles in one-room houses was 92, in two-room houses it was 46, in three-room houses it was 25, and in four rooms and over it was 15. The Board proposed to make the disease notifiable, appoint a special *ad hoc* staff of visiting nurses for infectious diseases, increased hospital facilities, and an increased service of health visitors. In 1923 a committee was appointed to inquire into puerperal morbidity and mortality. The deaths of women in childbirth in Scotland numbered over 700 annually, and the amount of sickness and disablement which did not result in death was very great. In their report the Committee expressed with confidence the view that puerperal morbidity and mortality were largely avoidable and could be reduced by improvement of the midwifery service and by the provision of antenatal care for the expectant mother. The Board had invited local authorities to submit detailed proposals on the lines suggested by the Committee.

No restriction would be placed on the development of maternity service and child welfare schemes otherwise provided that the Board were satisfied with the proposals on the merits. The rationing scheme for calculating grant on food and milk expenditure had now been withdrawn and grant was paid at the full rate of 10*s.* per £ on expenditure, supported by the certificate of a responsible medical officer that he considered after examination that additional nourishment was necessary.

The opening of new venereal disease centres was proceeding steadily, but it was disquieting to observe that no less than 53 per cent. of patients discontinued treatment without the sanction of the medical officer. This fact made it necessary to consider whether local authorities did not require further powers to deal more effectively with venereal disease.

" Sleeping sickness " was increasing. It was hoped that investigations that were being made would before long lead to the discovery of an effective method of treatment. During 1923 and the current year a number of cases of infective jaundice had occurred in East Lothian and Midlothian. The majority of those affected were miners, and all worked in the neighbourhood of two contiguous pits. There had been 15 cases and four deaths. The disease was associated with a disease of rats, which was due to the same organism, and though it had not been definitely settled how the disease was conveyed from rat to man, it was necessary that as far as possible rats should be trapped and killed and their access to the pits prevented. The matter of infective jaundice was being dealt with by the Medical Research Department and had now been referred to the Mines Department. The Board were awaiting the result. In conclusion, Mr. Stewart referred to the distress in the Highlands and Islands, and said that the Board were paying attention to this matter in the hope that in the near future they might be able to make recommendations dealing with the general health of the community in the direction of solving this problem.

HOUSE OF LORDS.

MONDAY, JULY 14TH.

Royal Commission on Lunacy.

THE LORD CHANCELLOR moved the following :—" In order to bring the Tribunals of Inquiry (Evidence) Act, 1921, into operation, it is expedient that a tribunal be established for inquiring into (1) the existing law and administrative machinery in England and Wales in connexion with the certification, detention, and care of persons who are or are alleged to be of unsound mind; and (2) the extent to which provision is or should be made in England and Wales for the treatment without certification of persons suffering from mental disorder." He explained that the object of the motion was to enable the Royal Commission on Lunacy to call witnesses and examine them on oath. The motion was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, JULY 9TH.

Medical Test of Temporary Civil Servants.

Mr. HORE-BELISHA asked the Parliamentary Secretary to the Admiralty, with reference to the examination which was contemplated for ex-Service men employed as temporary civil servants under the Admiralty, whether he was aware of the great hardship which such examination imposed upon those who had done good service to the country, and why they had now to submit to an educational, departmental, and medical test to ascertain whether they were fit for retention in their present capacity, although they had given every satisfaction and had demonstrated their ability; and whether he could exempt these men from the examination proposed or their dismissal as the result of such examination.—Mr. AMMON replied: The examination which was held on July 3rd was of a comparatively simple character and suited to the age of the ex-Service competitors, and should not have imposed great hardship on any of the candidates. Appointments of temporary clerks to the clerical grades of the Civil Service are made by examination and this practice has been endorsed by Lord Southborough's Committee in its final report. No person can be given an established post until he has satisfied the Civil Service Commissioners of his physical fitness, amongst other factors. As I have already explained to the hon. Member, there is provision for the medical standard to be relaxed in the favour of men whose health has been impaired as a result of service in the forces in the late war.

New Mental Hospitals.

Mr. ROBERT RICHARDSON asked the Minister of Health what schemes were in contemplation for the building of new asylums and other mental institutions; in view of the declaration in 1922 of a surplus of 18,000 beds, would he explain why such extension was necessary; and whether it was the intention of the Board of Control to offer this increased accommodation to uncertified cases for the purpose of retaining them under their own authority instead of encouraging the provision of hospitals apart from lunacy, and run by the health committees of local authorities for the benefit of slight and non-dangerous cases, where they could recover without risk of stigma.—Mr. WHEATLEY replied: Only one scheme for the building of a new mental hospital is in contemplation, but further accommodation will be needed in the near future. The figure of 18,000 beds was an estimate made at the end of 1920; but, for various reasons, certain schemes then foreshadowed were not proceeded with. On Jan. 1st in the present year there were, in fact, only 4754 vacant beds. As the average annual increase of certified patients during the last two years has been at the rate of 3266, it is obvious that further provision is necessary. The question whether provision should be made for the early treatment of cases of mental disorder without certification is one of the principal matters referred to the Royal Commission recently appointed.

Hendon Institute Lymph.

Mr. BLACK asked the Minister of Health whether any records had been kept showing the pedigree of the lymph used at the Hendon Institute.—Mr. WHEATLEY replied: Yes, Sir.

Court of Appeal for Certified Lunatics.

Mr. ROBERT RICHARDSON asked the Minister of Health if his attention had been called to the remarks of Lord Justice Scrutton, on the occasion of the appeal against Harnett, in regard to the necessity for a thorough examination into the grounds on which an alleged lunatic was imprisoned as well as the desirability that he should at certain intervals during detention have the opportunity of demanding an independent investigation into his case; and, in the interests of justice to the public, would he take steps to institute a court of appeal for those imprisoned in asylums, after the analogy of the court of appeal provided for other classes of prisoners.—Mr. WHEATLEY replied: The points raised in this question come within the terms of reference of the Royal Commission on Lunacy and Mental Disorder, which has just been appointed; and any action in the matter should, I think, be deferred until the Royal Commission has reported.

Bodies of Paupers for Medical Dissection.

Mr. PENNY asked the Minister of Health whether he was aware that his department had officially approached the Kingston board of guardians with a view to making arrangements for that authority to hand over the bodies of dead friendless paupers to the London hospitals for dissection purposes; in view of the odium which such a step threw upon the guardians, many of whom were averse to the proposal, would he reconsider the whole matter, and would he say whether similar overtures had been made to other boards of guardians throughout the country.—Mr. WHEATLEY replied: Yes, Sir, the application to Kingston guardians was made with my authority and in this matter I have followed the invariable practice of my predecessors of all parties and of successive Home Secretaries with whom the responsibility under the Anatomy Acts rested prior to the transfer of this duty to the Minister of Health. I recognise the very natural objections which such a proposal must at first sight provoke, but I am satisfied that there is no alternative which would not have disastrous effects on surgical and medical education, and ultimately on the treatment of the sick. The effective teaching of anatomy and operative surgery, which form an essential part of medical education, will become impossible unless the necessary subjects can be made available for practical instruction. If anatomy cannot be taught by the examination of the dead it will have to be learned by experiment on the living; and except in the case of the comparatively small number of students who could afford to go abroad for their anatomical study, young practitioners would be compelled to acquire by experimenting on their patients the knowledge which it would have been impossible to impart to them in the medical schools. Many other unions throughout the country, including those adjacent to Kingston, are coöperating with the department in this matter, and I am glad to learn that it is generally recognised by the guardians that the poor would be the first to suffer if medical students could not obtain the necessary teaching without going abroad for it. I would add that the Anatomy Acts contain detailed provisions as to the conditions under which bodies are to be used for this purpose, and these provisions are stringently enforced under the constant supervision of H.M. Inspector of Anatomy. All bodies used for this purpose are duly interred within the prescribed period after a religious service appropriate to the denomination to which the deceased belonged and the place of burial is carefully recorded. It is impracticable to rely for this purpose upon those who voluntarily leave their bodies by will to be used for anatomical teaching, since the number is wholly insufficient. I would add that the reason for seeking the coöperation of the guardians is not the poverty of the persons concerned, but the fact that they have no known or traceable relatives to claim the body for burial, and therefore there is no one to be distressed by the use of the body for purposes which are vitally necessary to the proper teaching of medicine.

Deaths from Small-pox, &c.

Mr. GILBERT asked the Minister of Health how many deaths had been registered this year from small-pox, measles, pneumonia, scarlet fever, diphtheria, influenza, and encephalitis lethargica.—Mr. WHEATLEY replied: According to the provisional figures received by the Registrar-General, the deaths registered in England and Wales in the quarter ended March 31st last included: Small-pox 3, measles 1741, scarlet fever 263, diphtheria 742, encephalitis lethargica 229. No separate figures are at present available of deaths from pneumonia or deaths from influenza. The returns for the second quarter ended June 30th are only now being received, and the corresponding figures for that quarter cannot yet be given, but I will furnish the hon. Member with these figures as soon as they are available.

Women Medical Officers and Antenatal Clinics.

Mr. COSTELLO asked the Minister of Health whether he was aware that in certain districts the antenatal and other clinics were not so successful as they otherwise would be, owing to a natural disinclination on the part of many women to go themselves or to take their adolescent daughters to clinics which were under the charge of men medical officers or assistant medical officers of health, especially in those districts where there was a woman assistant medical officer available for such work; and whether he will take steps to ensure that, at any rate in districts where there were already women assistant medical officers, the work in connexion with women and the older girls should be undertaken by the women medical officers and not by the men, and that upon vacancies occurring in public health appointments, the duties of which consisted wholly or mainly of the kind of work above mentioned, such vacancies should be filled by women in preference to men.—Mr. WHEATLEY replied: I have no information to support the statement in the first part of the question. As regards the second part, while I favour the employment of women medical officers to take charge of antenatal clinics, I am not prepared to require that this should be done in all cases.

Free Supply of Insulin by Poor-law Authorities.

Captain REGINALD TERRELL asked the Minister of Health if, in view of the reduction of the price of insulin, it was supplied free by all Poor-law authorities on the recommendation of their respective medical officers.—Mr. WHEATLEY replied: I have no reason to suppose that Poor-law authorities are not supplying insulin in all proper cases in which application is made to them and supported by their medical officers.

Women Workers in Hospitals.

Miss JEWSON asked the Minister of Pensions whether the recent reduction in the wages of women working in hospitals run by the Ministry of Pensions had been general; and, if so, on whose instructions.—Mr. J. W. MUIR (Parliamentary Secretary to the Ministry of Pensions) replied: No general reduction has been made in the rates of pay of women employed in Ministry institutions; but in view of the fall in the cost of living since these rates were originally fixed

Impressed with the importance of the subject, the Board of Health had recently appointed a Departmental Committee, presided over by Lord Mackenzie, "to inquire into and to report upon the extent and nature of the inadequacy of the present hospital and ancillary services in Scotland, and to make recommendations for the development and maintenance of these services to meet the needs of the community."

Mortality from Tuberculosis.

Slowly but steadily the mortality from tuberculosis was lessening. In 1914 the deaths from that disease numbered 7696, whereas in 1923 they had fallen to 5786. In 1894 the death-rate in Scotland from pulmonary tuberculosis was 172 per 100,000 of the population; in 1914 the corresponding rate had fallen to 104, and in 1923 it had been still further reduced to 81. In respect of pulmonary tuberculosis Scotland had now a lower death-rate than England and Ireland. In the same period of 30 years the death-rate from non-pulmonary tuberculosis had fallen from 63 per 100,000 of the population in 1894 to 58 in 1914 and 36 in 1923. Notwithstanding the fact that the death-rate from this form of the disease showed a fall of 38 per cent. since 1914, Scotland occupied the unenviable position of having the highest death-rate of any of the three countries from non-pulmonary tuberculosis. But he had great hopes that the efforts of the local authorities would soon produce beneficial results which would be reflected in a still further substantial diminution of the death-rate.

There had been a substantial addition to the number of sanatorium and hospital beds reserved for the treatment of this disease. In 1918, at the close of the war, the number of such beds was 2590; to-day there were 3953 beds, and when the extensions, particularly in Glasgow, were finished they would have over 4800 beds reserved for the treatment of this disease. Local authorities must be encouraged to carry on and extend their activities where necessary. The local authorities would now receive in grant 50 per cent. of all reasonable expenditure in connexion with the treatment of this disease.

Maternity and Child Welfare.

With regard to maternity and child welfare in 1923, the deaths under 1 year numbered 80,825, equivalent to a death-rate of 78·9 per 1000 births. This was the lowest infantile death-rate ever recorded for Scotland. The deaths for 1923 over 1 year and under 5 years numbered 4926, equivalent to 12·3 per 1000 children within those ages. Here, again, the death-rate was the lowest on record for Scotland. In 1915 14,441 infants died under 1 year, equivalent to a death-rate of 126·5 per 1000 births, and 9120 children from 1 year to 5 years died, equal to a death-rate of 22·5 per 1000 children of those ages. Unfortunately, while the process of reducing the mortality among infants had been continuous, it was far from being a steady progress. In the first quarter of 1924 the infantile mortality-rate in Scotland rose to 132 per 1000 births, against 98 for the corresponding quarter in 1923. Only in June did the death-rate among children return to a less alarming level. In large measure this high mortality was due to a widespread epidemic of measles and whooping-cough, and to other diseases such as pneumonia that followed these infections. The Scottish Board of Health had issued a circular to local authorities with regard to the further control and treatment of these epidemic diseases, and a special sum of £10,000 had been set aside as part of the maternity and child welfare grant which would be distributed in a manner designed to encourage local authorities to institute further measures for the preservation of child life from the ravages of these very deadly diseases.

A special inquiry in 1908 revealed the following general facts regarding measles, which, like tuberculosis, was a poverty disease. The death-rate from measles in one-room houses was 92, in two-room houses it was 46, in three-room houses it was 25, and in four rooms and over it was 15. The Board proposed to make the disease notifiable, appoint a special *ad hoc* staff of visiting nurses for infectious diseases, increased hospital facilities, and an increased service of health visitors. In 1923 a committee was appointed to inquire into puerperal morbidity and mortality. The deaths of women in childbirth in Scotland numbered over 700 annually, and the amount of sickness and disablement which did not result in death was very great. In their report the Committee expressed with confidence the view that puerperal morbidity and mortality were largely avoidable and could be reduced by improvement of the midwifery service and by the provision of antenatal care for the expectant mother. The Board had invited local authorities to submit detailed proposals on the lines suggested by the Committee.

No restriction would be placed on the development of maternity service and child welfare schemes otherwise provided that the Board were satisfied with the proposals on the merits. The rationing scheme for calculating grant on food and milk expenditure had now been withdrawn and grant was paid at the full rate of 10*s.* per £ on expenditure, supported by the certificate of a responsible medical officer that he considered after examination that additional nourishment was necessary.

The opening of new venereal disease centres was proceeding steadily, but it was disquieting to observe that no less than 53 per cent. of patients discontinued treatment without the sanction of the medical officer. This fact made it necessary to consider whether local authorities did not require further powers to deal more effectively with venereal disease.

"Sleeping sickness" was increasing. It was hoped that investigations that were being made would before long lead to the discovery of an effective method of treatment. During 1923 and the current year a number of cases of infective jaundice had occurred in East Lothian and Midlothian. The majority of those affected were miners, and all worked in the neighbourhood of two contiguous pits. There had been 15 cases and four deaths. The disease was associated with a disease of rats, which was due to the same organism, and though it had not been definitely settled how the disease was conveyed from rat to man, it was necessary that as far as possible rats should be trapped and killed and their access to the pits prevented. The matter of infective jaundice was being dealt with by the Medical Research Department and had now been referred to the Mines Department. The Board were awaiting the result. In conclusion, Mr. Stewart referred to the distress in the Highlands and Islands, and said that the Board were paying attention to this matter in the hope that in the near future they might be able to make recommendations dealing with the general health of the community in the direction of solving this problem.

HOUSE OF LORDS.

MONDAY, JULY 14TH.

Royal Commission on Lunacy.

THE LORD CHANCELLOR moved the following:—"In order to bring the Tribunals of Inquiry (Evidence) Act, 1921, into operation, it is expedient that a tribunal be established for inquiring into (1) the existing law and administrative machinery in England and Wales in connexion with the certification, detention, and care of persons who are or are alleged to be of unsound mind; and (2) the extent to which provision is or should be made in England and Wales for the treatment without certification of persons suffering from mental disorder." He explained that the object of the motion was to enable the Royal Commission on Lunacy to call witnesses and examine them on oath. The motion was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, JULY 9TH.

Medical Test of Temporary Civil Servants.

Mr. HORE-BELISHA asked the Parliamentary Secretary to the Admiralty, with reference to the examination which was contemplated for ex-Service men employed as temporary civil servants under the Admiralty, whether he was aware

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College Sir John Bland-Sutton was re-elected President and Mr. H. J. Waring re-elected and Mr. Walter G. Spencer elected Vice-Presidents for the ensuing year. Mr. W. McAdam Eccles, Mr. Wilfred Trotter, and Sir Charles Gordon-Watson, having been duly elected at the meeting of Fellows on July 3rd, were introduced and took their seats as members of the Council. Mr. Donald Kennedy Cassels, B.A. Camb., was appointed Assistant to the Secretary during the ensuing year. Mr. R. H. Burne was re-elected Pathological Curator and Sir Frank Colyer was re-elected Hon. Curator of the Odontological Collection. Mr. Cecil F. Beadles was reappointed Assistant Pathological Curator and Mr Clement E. Shattock was reappointed Pathological Assistant in the Museum for the ensuing year.—On the advice of the Museum Committee the office of Pathological Curator of the Museum was left vacant for the present. Mr. T. W. P. Lawrence, F.R.C.S., was invited to advise and assist in rearranging and revising the series of special pathology in the Museum.—It was announced that the Library of the College would be closed in August as well as in September for the purpose of cleaning and re-decorating.—A letter of July 3rd was read from the Chairman of the Lister Memorial Committee reporting that thr Lister Medal for distinguished contributions to surgical science had been awarded to Sir W. Watson Cheyne, Bart., and that, in compliance with the conditions of the Trust, Sir Watson Cheyne had undertaken to give an address at the Royal College of Surgeons on some date in 1925 convenient to the President and Council.

The following gentlemen were elected professors and lecturers for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith: Six lectures on the Evolution of the Higher Primates. R. Lawford Knaggs: One lecture on Osteitis Deformans and its Connexion with Osteitis Fibrosa and Osteomalacia. V. Zachary Cope: One lecture on Extravasation of Bile. A. Herapath Todd: One lecture on Syphilitic Arthritis. Victor E. Negus: One lecture on Disorders of the Mechanism of the Larynx. H. P. Winsbury White: One lecture on the Pathology of Hydronephrosis. Stanford Cade: One lecture on Regional Anæsthesia.

Arris and Gale Lecturers.—Cecil P. G. Wakeley: One lecture on the Ætiology, Pathology, and Treatment of Ectopic and Imperfect Descent of the Testis. George Scott Williamson: Two lectures on the Anatomy and Physiology of the Thyroid Apparatus.

Erasmus Wilson Lecturer.—Gilbert W. de Poulton Nicholson: Three lectures on the Nature of Tumour Formation.

Arnott Demonstrator.—Sir Arthur Keith: Six demonstrations on the Contents of the Museum.

Licences to practise dentistry were conferred upon the following 63 candidates, who have passed the requisite examinations and have complied with the by-laws:—

L. P. Allen, London; L. N. Alley, Manchester; P. R. Asplet, Manchester and Royal Dental; J. Badenhorst, Royal Dental; E. A. Balkwill, Birmingham; W. J. Barnard, Guy's; D. C. Blyth, Royal Dental; W. R. Booth, London; W. L. Breese, Royal Dental; D. F. G. Came, Middlesex; H. Cantor and P. L. Carnall, London; S. D. Cloete, Royal Dental; A. Critchley, Manchester; E. J. B. Curtis, Guy's; J. M. Davies, Univ. Coll.; A. E. Davis and C. E. Day, Royal Dental; R. S. De Bruyn, Guy's; M. B. Deverell and A. Dreaper, Royal Dental; P. J. Du Toit and E. F. Farmer, Guy's; A. Fleming, Durham; C. H. Fox and W. H. Foy, Guy's; P. D. Gausden, London; E. E. Gibson, Guy's; Sarah Glasstone, Univ. Coll.; F. H. Goddard, Guy's; J. F. Godfrey, Birmingham; H. E. Hovell and V. W. Humpherson, Royal Dental; K. Huxtable, Bristol; N. H. Jenkins, Royal Dental; A. F. King, Guy's; F. W. Lambert and A. P. McClare, London; M. Marais, Royal Dental; P. M. Margand, Univ. Coll.; J. W. Mitchell, London; F. E. Padgett and L. Page, Royal Dental; Marjorie E. C. Page, Univ. Coll.; N. Parkinson and K. F. Pelley, Guy's; H. L. Pretty, London; P. Rosen, Royal Dental; J. C. Rowbotham, Guy's; C. G. Searle, Univ. Coll.; W. H. Shapland, London; Ita N. Shatz, Royal Dental; N. H. Simmonds, Bristol; M. Sperber, S. G. A. Stephenson, and B. J. Swyer, London; J. H. Threlfall, Univ. Coll.; G. G. T. Tregarthen, Guy's; W. A. Turner, Royal Dental; H. P. R. Williams, Guy's; R. N. Winnett, London; R. Woodcock, Sheffield; and B. Woolich, London.

The undermentioned diplomas were conferred (in conjunction with the Royal College of Physicians of London):—

Diploma in Public Health.—H. L. Barker and Joyce R. Batten, Univ. Coll.; W. G. Booth, King's Coll.; L. P. Costobadie, Cambridge and Manchester; A. Crawford, Glasgow and Roy. Inst. Public Health; B. B. Dalal, Bombay and Univ. Coll.; Edith M. P. Davies, Royal Free and King's Coll.; S. R. E. Davies, Cambridge and St. Bart.'s; Helen M. Du Buisson, King's Coll.; Mary Esslemont, Aberdeen and King's Coll.; Gwladys Evans, Univ. Coll.; Dorothy J. L. Gillie, Glasgow and Univ. Coll.; P. C. C. Garnham, St. Bart.'s; G. M. Hargreaves, [illegible] and Univ. Coll.; Marjorie C. Hankins, Roy. Inst. Public Health; N. R. Jenkins, Cardiff and Roy. Inst. Public Health; Elspeth H. R. Livingstone, Edinburgh and Univ. Coll.; V. A. Luna, Guy's and Univ. Coll.; Kathleen F. Matthews, Univ. Coll.; Alice D. Pocock, Royal Free and Univ. Coll.; A. T. W. Powell, Guy's; I. N. O. Price, Univ. Coll.; Violet Reade, Royal Free and King's Coll.; Grace Stevenson, Otago and Univ. Coll.; Emma M. Store, Royal Free and Univ. Coll.; E. Tagoe, Cambridge and Univ. Coll.; Blanchette Thomas, Univ. Coll.; P. Thwaites, St. Bart.'s; E. H. Wilkins, Dublin and King's Coll.; Gwendolen Wilson, Aberdeen and Univ. Coll.; and J. G. Wilson, King's Coll.

Diploma in Laryngology and Otology.—W. R. Beavis, Birmingham Ear and Throat Hosp.; J. B. Cavenagh, Oxford and St. Thomas's; J. Hare, Durham and Roy. Army Med. Coll.; H. I. Marriner, St. Thomas's; and T. G. Wynne, Melbourne and Central London Throat and Nose Hosp.

Diploma in Psychological Medicine.—J. S. Harris, Edinburgh and Hanwell; W. J. T. Kimber, St. Thomas's and Hill End; N. Macleod, Edinburgh, Leeds, and York; E. G. T. Poynder, Middlesex and Epsom; and D. Slight, Edinburgh.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following candidates passed the terminal examination of the seventy-fifth session of the School (April to July, 1924) with distinction:—

A. W. Grace (winner of "Lalcaca" and "Duncan" medals), B. B. Yodh, W. Rae, T. Creaser, R. B. Wallace, G. C. Ramsay, and R. Dick.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

FINAL M.B. AND CH.B. EXAMINATION.

Margaret A. Bromhall, W. C. V. Brothwood, T. A. Brown, *J. A. Crowther, Madge E. Edwards, Reginald Ellis, A. G. Forbes, Philip Gregory, Edward Holmes, †Winifred L. Horton, W. G. Howson, *Phyllis I. Kaufmann, David Kemp, *‡Hilda M. Linford, F. R. Lockhart, Gladys F. A. McLean, Alice M. Orrell, Thomas Peirson, Samuel Pope, L. J. Prosser, Albert Riley, W. M. Roberts, Eileen Sheehan, Dorothy Simmons, John Sims, G. S. Smith, James Troup, H. M. Turner, C. L. Walker, Eric Whiteside, †Charles Wilcocks, and Geoffrey Williamson.

* Second-class honours. † Distinction in Medicine.
‡ Distinction in Forensic Medicine.

Obstetrics and Surgery.—A. R. Addey-Redfern, J. K. Barr, C. V. Brown, Stella H. Brown, Elsie Catlow, William Chadwick, S. F. Clegg, Jenny D. Craig, Stanley Devine, Florence M. Duckworth, Charles Eccleston, J. D. Farquhar, R. A. Ferguson, James Haslam, G. H. Hayle, §A. H. Heyworth, Elizabeth G. Humble, A. M. MacGill, William Mottershead, Ethel Morris, Henry Penman, T. W. Rothwell, H. T. Simmons, A. B. Slack, Robert Slater, H. C. Smith, Ronald Walshaw, S. E. Ward, Samuel Whalley, R. M. Williams, S. P. Wilson, K. K. Wood, P. B. Wood, and Frank Yates.

§ Distinction in Obstetrics.

Forensic Medicine and Hygiene and Preventive Medicine.—R. S. Adam, William Chadwick, T. E. Davies, C. R. Fielding, A. H. Heyworth, J. N. Hudson, T. W. Rothwell, R. F. Stubbs, and J. M. Yoffey.

Forensic Medicine.—Solomon Bernstein, J. W. Graham, Robert Slater, and A. R. Somerford.

Obstetrics.—C. T. Marshall, Joseph Shlosberg, E. J. Warburton, and J. M. Yoffey.

Surgery.—P. G. Johnson and R. F. Stubbs.

Medicine.—J. M. Yoffey.

Hygiene and Preventive Medicine.—Anne H. Glancy and E. J. Warburton.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Part II.—L. C. F. Chevens, H. D. Cormac, T. W. Davidson, W. J. Lynch, and W. R. McGlashen.

DIPLOMA IN PUBLIC HEALTH.

Part II.—F. R. Ferguson Marjorie A. Grant, Gladys J. C. Russell, Enid F. Stowell, and Ethel White.

The Vice-Chancellor, in his annual report for the session 1923–24, states that the number of students in the Faculty of Medicine was 686, of whom 128 were women. The following comparative statement shows the total number of students in the Faculty of Medicine: 353 (1917–18), 538 (1918–19), 771 (1919–20), 754 (1920–21), 734 (1921–22), 711 (1922–23), 686 (1923–24). Amongst the donations to the medical faculty were £200 from Prof. A. V. Hill, F.R.S., for the establishment of a prize in biochemistry, and £2028 from the trustee of the late Mrs. Morrison Watson for the foundation of an exhibition or scholarship in anatomy in memory of her husband, who was for many years professor of anatomy in Owens College and the University. In October, 1923, the new curriculum was inaugurated according to the recommendation of the General Medical Council, which entails six years' work in the medical school for the degree course. A student will not be registered by the General Medical Council as a medical student until he has passed the science examination in chemistry and physics. The longer period of studentship did not reduce the entries below the normal in number, as 53 students were registered for the first year of the degree course in October. A course for the Diploma in Psychological Medicine, instituted before the war, was given this session and was attended by six qualified men. New regulations for the Diploma in Public it has been necessary to pass them under review, and where it has been found that the rate paid is in excess of the local rate for similar work or of the rates paid in other comparable institutions, a small reduction has been made. The staff affected is under 20 per cent. of the total number whose wages have been reconsidered. I am sending the hon. Member a comparative statement of the old and the new rates.

THURSDAY, JULY 10TH.

Incurable Tuberculosis Patients at Maidstone.

Major **WILLIAMS** asked the Minister of Pensions if, by legislative or administrative action, he could place on a permanent and more satisfactory basis the pensions of men suffering from incurable tuberculosis in Preston Hall, near Maidstone.—Mr. F. O. **ROBERTS** replied: The men suffering from tuberculosis who are inmates of Preston Hall are in that institution either for periods of treatment or for treatment combined with a course of training. Such cases are not, therefore, in a condition in which a final award could properly be determined in the interests of the men themselves.

Pensioners and Final Awards.

Mr. **AYLES** asked the Minister of Pensions whether, in view of the general dissatisfaction existing in regard to the system of making final awards to pensioners whose disabilities were assessed at less than 20 per cent., he would take steps to abolish this system at an early date.—Mr. F. O. **ROBERTS** replied: I am not at present convinced that the course suggested, which would involve amendment of the Act, is called for. Cases of the class referred to, like those of any other class, in which it is shown that the last award was erroneously declared final, will, it is anticipated, be met by the arrangements which have recently been introduced to deal with cases of serious error. I am carefully watching the operation of these arrangements. I may perhaps remind my hon. friend that cases of minor disablement have never, under the Pensions Warrants, been entitled to a continuing pension, and their position in this respect has not been affected by the final award.

Accommodation at Roehampton Hospital.

Mr. **BECKER** asked the Minister of Pensions if he could make inquiries into the accommodation at the Roehampton Hospital; and could steps be taken to speed up the fitting of artificial legs so that ex-Service men did not lose their day's work.—Mr. F. O. **ROBERTS** replied: The accommodation at Roehampton Hospital is ample, and I do not think that any avoidable delay occurs in fitting or repairing artificial legs. Moreover, every pensioner has been supplied with a duplicate leg, to be used while the first is under repair and the necessity for personal attendance at the hospital is thus, for the most part, avoided after a first fitment.

Small-pox Deaths in 1923.

Mr. **BROMFIELD** asked the Minister of Health what were the ages of the persons registered as having died from small-pox in the year 1923, and in what towns or villages they occurred.—Mr. **WHEATLEY** replied: The particulars of the deaths from small-pox in England and Wales during 1923 are as follows:—

Age of deceased.	Deceased's place of—	
	Death.	Residence.
1 month.	Small-pox hospital. Brockworth, Gloucester.	Gloucester.
10 months.	,,	,,
5 years.	,,	,,
63 ,,	,,	,,
28 ,,	Joyce Green Hospital. Dartford.	Neasden, Willesden.
55 ,,	,,	Battersea.
17 ,,	Chester.	Chester.

MONDAY, JULY 14TH.

A Medical Staff and Trade-Unionism.

Mr. **EDMUND HARVEY** asked the Minister of Health whether his attention had been called to the action of the guardians of the West Ham Union in informing the officers in their service, including the whole-time medical staff. matron, nurses, and indentured probationer nurses of the Whipps Cross Hospital, that they desired them to become members of a trade-union affiliated to the Trade Union Congress, and to the decision of the board of guardians to review the position with reference to existing officers at the expiration of two months from the adoption by the board of this recommendation; whether he has had any communication with the board as to their action in this matter; and, whether, in view of the special difficulties that the action of the guardians had caused to the medical and nursing staff, he would take steps to prevent the imposition of such a regulation by the board of guardians.—Mr. **GREENWOOD** replied: My right hon. friend is aware of the action of the guardians though he has not been in direct communication with them. The guardians do not appear to be exceeding their legal powers, and my right hon. friend does not see that the matter is one in which he could usefully take any action.

Purchases of Dangerous Drugs in Britain.

Captain **WEDGWOOD BENN** asked the Home Secretary how much opium was purchased by factories in Great Britain in 1923; how much morphia, how much heroin, and how much codeine was manufactured by the factories; and how much of each of these narcotics was sent abroad. —Mr. **HENDERSON** replied: I assume that by "factories" the hon. and gallant Member means only those firms which are licensed under the Dangerous Drugs Acts to manufacture morphine and heroin and their salts. The amount of opium imported and purchased by those firms in 1923 was 125,833 lb. The amount of morphine and its salts manufactured in 1923 was 254,337 oz., of which, however, 166,397 oz. were converted into heroin, codeine, or other derivatives of opium, leaving a net total of 87,940 oz., of which 78,611 oz. were exported. The amount of heroin manufactured in 1923 was 11,575 oz., and the total exports of heroin amounted to 12,011 oz. The amount of codeine manufactured in 1923 was 162,036 oz., of which 160,910 oz. were exported by the manufacturers. As codeine is not subject to the Dangerous Drugs Acts, its movements are not recorded after it leaves the manufacturers, and it is not therefore known whether any other amounts of codeine were exported during 1923 by persons other than the manufacturers.

The Services.

ROYAL ARMY MEDICAL CORPS.

ARMY RESERVE OF OFFICERS.

Army Dental Corps: Lt. P. Colk, from Green Howards, Res. of Off., to be Lt.

TERRITORIAL ARMY.

Maj. J. W. Craven to be Lt.-Col. and to Comd. 149th (Northern) Field Ambulance, vice Lt.-Col. F. Hawthorn vacated on completion of tenure of comd.

Lt. H. M. Brown to be Capt.

ROYAL AIR FORCE.

H. W. Corner is granted a short service commission as a Flying Officer.

Flight Lt. T. A. G. Hudson is transferred to the Reserve, Class D.2.

Flying Officer K. R. Smith relinquishes his temporary commission on ceasing to be employed.

SIR MALCOLM MORRIS MEMORIAL FUND.

Dr. Howard Mummery, the hon. secretary of the Committee, sends the following supplementary list of subscribers to this Fund. The total to date is £409 8s. 2*d*.

Dr. George C. Andrews and Mrs. Angell.
Sir Anthony A. Bowlby and Dr. Walter Broadbent.
Sir Felix Cassel and Sir Francis H. Champneys.
Dr. Mary Douie and Sir Dyce Duckworth.
Lady Emmott.
Mr. Walter Farris, Dr. Wilfrid S. Fox, and Mr. H. W. Fraser.
Mrs. James Gow, Hon. Walter Guinness, M.P.
Dr. C. O. Hawthorne and Mr. Edward M. House.
Mr. Warwick James and Mr. and Mrs. L. Jopling.
Mr. Richard Lluellyn.
Dr. G. M. MacKee, Dr. Henry E. Michelson, Dr. R. Pryce Mitchell, Lady Morris, Miss C. Morris, Miss G. Morris, Mr. Harold S. Morris, K.C., and Miss Hilda Morris.
National Council for Combating Venereal Diseases, N.C.C.V.D., Hull Branch, and N.C.C.V.D., Plymouth Branch.
Mr. A. E. Hayward Pinch and Mr. W. A. Posnett.
Mr. and Mrs. John Rivers and Sir Leonard Rogers.
Mr. Henry S. Saint, Dr. Henry Semon, and Mr. C. F. Sutcliffe.
Captain Oskar Teichman.
Miss Edith Wethered and Mr. A. Hamilton Wood.

Further subscriptions will be gratefully acknowledged if forwarded to the hon. treasurers, Sir Malcolm Morris Memorial Fund, at 12, Stratford-place, London, W. 1.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College Sir John Bland-Sutton was re-elected President and Mr. H. J. Waring re-elected and Mr. Walter G. Spencer elected Vice-Presidents for the ensuing year. Mr. W. McAdam Eccles, Mr. Wilfred Trotter, and Sir Charles Gordon-Watson, having been duly elected at the meeting of Fellows on July 3rd, were introduced and took their seats as members of the Council. Mr. Donald Kennedy Cassels, B.A. Camb., was appointed Assistant to the Secretary during the ensuing year. Mr. R. H. Burne was re-elected Pathological Curator and Sir Frank Colyer was re-elected Hon. Curator of the Odontological Collection. Mr. Cecil F. Beadles was reappointed Assistant Pathological Curator and Mr Clement E. Shattock was reappointed Pathological Assistant in the Museum for the ensuing year.—On the advice of the Museum Committee the office of Pathological Curator of the Museum was left vacant for the present. Mr. T. W. P. Lawrence, F.R.C.S., was invited to advise and assist in rearranging and revising the series of special pathology in the Museum.—It was announced that the Library of the College would be closed in August as well as in September for the purpose of cleaning and re-decorating.—A letter of July 3rd was read from the Chairman of the Lister Memorial Committee reporting that thr Lister Medal for distinguished contributions to surgical science had been awarded to Sir W. Watson Cheyne, Bart., and that, in compliance with the conditions of the Trust, Sir Watson Cheyne had undertaken to give an address at the Royal College of Surgeons on some date in 1925 convenient to the President and Council.

The following gentlemen were elected professors and lecturers for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith: Six lectures on the Evolution of the Higher Primates. R. Lawford Knaggs: One lecture on Osteitis Deformans and its Connexion with Osteitis Fibrosa and Osteomalacia. V. Zachary Cope: One lecture on Extravasation of Bile. A. Herapath Todd: One lecture on Syphilitic Arthritis. Victor E. Negus: One lecture on Disorders of the Mechanism of the Larynx. H. P. Winsbury White: One lecture on the Pathology of Hydronephrosis. Stanford Cade: One lecture on Regional Anæsthesia.

Arris and Gale Lecturers.—Cecil P. G. Wakeley: One lecture on the Ætiology, Pathology, and Treatment of Ectopic and Imperfect Descent of the Testis. George Scott Williamson: Two lectures on the Anatomy and Physiology of the Thyroid Apparatus.

Erasmus Wilson Lecturer.—Gilbert W. de Poulton Nicholson: Three lectures on the Nature of Tumour Formation.

Arnott Demonstrator.—Sir Arthur Keith: Six demonstrations on the Contents of the Museum.

Licences to practise dentistry were conferred upon the following 63 candidates, who have passed the requisite examinations and have complied with the by-laws:—

L. P. Allen, London; L. N. Alley, Manchester; P. R. Asplet, Manchester and Royal Dental; J. Badenhorst, Royal Dental; E. A. Balkwill, Birmingham; W. J. Barnard, Guy's; D. C. Blyth, Royal Dental; W. R. Booth, London; W. L. Breese, Royal Dental; D. F. G. Came, Middlesex; H. Cantor and P. L. Carnall, London; S. D. Cloete, Royal Dental; A. Critchley, Manchester; E. J. B. Curtis, Guy's; J. M. Davies, Univ. Coll.; A. E. Davis and C. E. Day, Royal Dental; R. S. De Bruyn, Guy's; M. B. Deverell and A. Dreaper, Royal Dental; P. J. Du Toit and E. F. Farmer, Guy's; A. Fleming, Durham; C. H. Fox and W. H. Foy, Guy's; P. D. Gausden, London; E. F. Gibson, Guy's; Sarah Glasstone, Univ. Coll.; F. H. Goddard, Guy's; J. F. Godfrey, Birmingham; H. E. Hovell and V. W. Humpherson, Royal Dental; K. Huxtable, Bristol; N. H. Jenkins, Royal Dental; A. F. King, Guy's; F. W. Lambert and A. P. McClare, London; M. Marais, Royal Dental; P. M. Margand, Univ. Coll.; J. W. Mitchell, London; F. E. Padgett and L. Page, Royal Dental; Marjorie E. C. Page, Univ. Coll.; N. Parkinson and K. F. Pelley, Guy's; H. L. Pretty, London; P. Rosen, Royal Dental; J. C. Rowbotham, Guy's; C. G. Searle, Univ. Coll.; W. H. Shapland, London; Ita N. Shatz, Royal Dental; N. H. Simmonds, Bristol; M. Sperber, S. G. A. Stephenson, and B. J. Swyer, London; J. H. Threlfall, Univ. Coll.; G. G. T. Tregarthen, Guy's; W. A. Turner, Royal Dental; H. P. R. Williams, Guy's; R. N. Winnett, London; R. Woodcock, Sheffield; and B. Woolich, London.

The undermentioned diplomas were conferred (in conjunction with the Royal College of Physicians of London):—

Diploma in Public Health.—H. L. Barker and Joyce R. Batten, Univ. Coll.; W. G. Booth, King's Coll.; L. P. Costobadie, Cambridge and Manchester; A. Crawford, Glasgow and Roy. Inst. Public Health; R. B. Dalal, Bombay and Univ. Coll.; Edith M. P. Davies, Royal Free and King's Coll.; S. R. E. Davies, Cambridge and St. Bart.'s; Helen M. Du Buisson, King's Coll.; Mary Esslemont, Aberdeen and King's Coll.; Gwladys Evans, Univ. Coll.; Dorothy J. L. Gallie, Glasgow and Univ. Coll.; P. C. C. Garnham, St. Bart.'s; G. M. Hargreaves, Edinburgh and Univ. Coll.; Marjorie C. Hawkins, Roy. Inst. Public Health; N. R. Jenkins, Cardiff and Roy. Inst. Public Health; Elspeth H. R. Livingstone, Edinburgh and Univ. Coll.; V. A. Luna, Guy's and Univ. Coll.; Kathleen F. Matthews, Univ. Coll.; Alice D. Pocock, Royal Free and Univ. Coll.; A. T. W. Powell, Guy's; I. N. O. Price, Univ. Coll.; Violet Reade, Royal Free and King's Coll.; Grace Stevenson, Otago and Univ. Coll.; Emma M. Store, Royal Free and Univ. Coll.; E. Tagoe, Cambridge and Univ. Coll.; Blanchette Thomas, Univ. Coll.; P. Thwaites, St. Bart.'s; E. H. Wilkins, Dublin and King's Coll.; Gwendolen Wilson, Aberdeen and Univ. Coll.; and J. G. Wilson, King's Coll.

Diploma in Laryngology and Otology.—W. R. Beavis, Birmingham Ear and Throat Hosp.; J. B. Cavenagh, Oxford and St. Thomas's; J. Hare, Durham and Roy. Army Med. Coll.; H. I. Marriner, St. Thomas's; and T. G. Wynne, Melbourne and Central London Throat and Nose Hosp.

Diploma in Psychological Medicine.—J. S. Harris, Edinburgh and Hanwell; W. J. T. Kimber, St. Thomas's and Hill End; N. Macleod, Edinburgh, Leeds, and York; E. G. T. Poynder, Middlesex and Epsom; and D. Slight, Edinburgh.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following candidates passed the terminal examination of the seventy-fifth session of the School (April to July, 1924) with distinction:—

A. W. Grace (winner of "Lalcaca" and "Duncan" medals), B. B. Yodh, W. Rae, T. Creaser, R. B. Wallace, G. C. Ramsay, and R. Dick.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

FINAL M.B. AND CH.B. EXAMINATION.

Margaret A. Bromhall, W. C. V. Brothwood, T. A. Brown, *J. A. Crowther, Madge E. Edwards, Reginald Ellis, A. G. Forbes, Philip Gregory, Edward Holmes, †Winifred L. Horton, W. G. Howson, *Phyllis I. Kaufmann, David Kemp, *‡Hilda M. Linford, F. R. Lockhart, Gladys F. A. McLean, Alice M. Orrell, Thomas Peirson, Samuel Pope, L. J. Prosser, Albert Riley, W. M. Roberts, Eileen Sheehan, Dorothy Simmons, John Sims, G. S. Smith, James Troup, H. M. Turner, C. L. Walker, Eric Whiteside, †Charles Wilcocks, and Geoffrey Williamson.

* Second-class honours. † Distinction in Medicine.
‡ Distinction in Forensic Medicine.

Obstetrics and Surgery.—A. R. Addey-Redfern, J. K. Barr, C. V. Brown, Stella H. Brown, Elsie Catlow, William Chadwick, S. F. Clegg, Jenny D. Craig, Stanley Devine, Florence M. Duckworth, Charles Eccleston, J. D. Farquhar, R. A. Ferguson, James Haslam, G. H. Hayle, §A. H. Heyworth, Elizabeth G. Humble, A. M. MacGill, William Mottershead, Ethel Morris, Henry Penman, T. W. Rothwell, H. T. Simmons, A. B. Slack, Robert Slater, H. C. Smith, Ronald Walshaw, S. E. Ward, Samuel Whalley, R. M. Williams, S. P. Wilson, K. K. Wood, P. B. Wood, and Frank Yates.

§ Distinction in Obstetrics.

Forensic Medicine and Hygiene and Preventive Medicine.—R. S. Adam, William Chadwick, T. E. Davies, C. R. Fielding, A. H. Heyworth, J. N. Hudson, T. W. Rothwell, R. F. Stubbs, and J. M. Yoffey.

Forensic Medicine.—Solomon Bernstein, J. W. Graham, Robert Slater, and A. R. Somerford.

Obstetrics.—C. T. Marshall, Joseph Shlosberg, E. J. Warburton, and J. M. Yoffey.

Surgery.—P. G. Johnson and R. F. Stubbs.

Medicine.—J. M. Yoffey.

Hygiene and Preventive Medicine.—Anne H. Glancy and E. J. Warburton.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Part II.—L. C. F. Chevens, H. D. Cormac, T. W. Davidson, W. J. Lynch, and W. R. McGlashen.

DIPLOMA IN PUBLIC HEALTH.

Part II.—F. R. Ferguson Marjorie A. Grant, Gladys J. C. Russell, Enid F. Stowell, and Ethel White.

The Vice-Chancellor, in his annual report for the session 1923–24, states that the number of students in the Faculty of Medicine was 686, of whom 128 were women. The following comparative statement shows the total number of students in the Faculty of Medicine: 353 (1917–18), 538 (1918–19), 771 (1919–20), 754 (1920–21), 734 (1921–22), 711 (1922–23), 686 (1923–24). Amongst the donations to the medical faculty were £200 from Prof. A. V. Hill, F.R.S., for the establishment of a prize in biochemistry, and £2028 from the trustee of the late Mrs. Morrison Watson for the foundation of an exhibition or scholarship in anatomy in memory of her husband, who was for many years professor of anatomy in Owens College and the University. In October, 1923, the new curriculum was inaugurated according to the recommendation of the General Medical Council, which entails six years' work in the medical school for the degree course. A student will not be registered by the General Medical Council as a medical student until he has passed the science examination in chemistry and physics. The longer period of studentship did not reduce the entries below the normal in number, as 53 students were registered for the first year of the degree course in October. A course for the Diploma in Psychological Medicine, instituted before the war, was given this session and was attended by six qualified men. New regulations for the Diploma in Public

Health, to meet the requirements set out by the General Medical Council, are now in force and the first course under the new regulations will commence in October next.

University of Aberdeen.—At the graduation ceremonial on July 10th degrees were conferred in the Faculty of Medicine on the following successful candidates :—

Doctor of Medicine.

*William Corner, *Robert J. Duthie, *Robert Forgan, *William I. Gerrard, Alastair R. Grant, Norman M. Maclennan, James Rannie, Robert Rannie, Henry J. Thomson, and Ian S. Thomson.

* Awarded commendation for thesis.

Master of Surgery.

Robert D. Lockhart and Foster H. B. Norrie.

Bachelor of Medicine and Bachelor of Surgery.

With First-class Honours.—*Anthony M. Hendry.

With Second-class Honours.—†Edward C. Chitty, †Richard B. Henderson, †John Innes, and †David West.

Ordinary Degree.—Redvers Anderson, John H. Arthur, Alexandra H. Benton. Kathleen Booth, Forbes Buchan, Andrew S. Burns, William Chisholm, Annie S. Clark, Mary Coutts, Edith Cran, Eirene V. Croll, James Crombie, John G. Currid, Francis R. Daniel, David Duncan, John C. Forbes, Stanley Forrest, Roderick M. Fraser, Ethel L. R. Galloway, Alexander D. Garden, †William C. Gorrod, James Hutcheon, Penuel M. Innes, Colin Joiner, Dudley W. Kirk, Flora H. G. Macdonald, John Macdonald, Thomas J. C. Macdonald, Robert H. Mackay, Roderick Mackay, Roderick Mackay, Alexander L. McLeod, Duncan Macleod, Christine Macrae, Charles P. Murray, Peter W. Philip, Alexander Reid, Alexander Reid, William M. Ritchie, Alexander Rose, †Cyril J. Sandford, William N. Simpson, James M. Smith, Alexander Stalker, Norman Taggart, George J. M. Teunon, William G. Watson, and Herbert M. Wright.

* Completed Final Examination with much distinction.
† Completed Final Examination with distinction.

Diploma in Public Health.

Catherine J. Clark, Eleanor M. Henderson, Charlotte S. Hendry, Roberta McLeish, Bethia M. Newlands, Violet M. G. Smith, John S. Taylor, and Gladys M. L. West.

The degree of honorary Doctor of Laws was conferred on Michael Comport Grabham, M.D., for unremitting services in scientific research.

Royal Faculty of Physicians and Surgeons of Glasgow.—At the monthly meeting of the Faculty held on July 7th William Kirkpatrick Anderson, M.B., Ch.B., (Glasgow), and Joseph Thomas Herbert Madill, M.B., Ch.B. (Chester), were admitted (after examination) as Fellows of the Faculty.

London (R.F.H.) School of Medicine for Women.—Research Fellowships, in connexion with the obstetrical and gynæcological unit, have been awarded to Miss Olive Rendel, M.D., B.S., and Miss Alfreda Baker, M.B., Ch.B. The donor of the funds for the Fellowships has also presented an electrocardiograph to the Royal Free Hospital. A "1916" bursary of the value of £50 a year for five years will be awarded to a student who has matriculated and who wishes to enter the school in October, 1924, to begin a full course of study for a medical degree. Full particulars can be obtained on application to the Warden and Secretary, 8, Hunter-street, London, W.C. 1. The Woman's Enquiry Bureau, No. 1, Quality-street, British Empire Exhibition, furnishes full particulars concerning the course of medical study at the school.

Study of Malaria in Eastern Europe.—The League of Nations Commission for the study of the incidence of malaria in Eastern Europe reached Moscow on July 13th in the course of its three months' tour. The Commission began its investigations in Jugoslavia at the end of May last, and has since visited Macedonia, Bulgaria, Roumania, and Poland. In Russia and the Ukraine the Commission is to study the principal malaria regions—namely, the Ukraine (Kharkov, Bakhmut and environs); Northern Caucasus (Rostov, Piatigorsk and neighbouring health resorts); the Volga region (Tsaritsyn, from Tsaritsyn to Nishni-Novgorod by boat along the Volga, Saratov Pokrovsk, the German Volga Republic; Kazan and the Tartar Republic). From Nishni-Novgorod the Commission will return to Moscow, where it will be shown the working of the Central Health Organisation and particularly the anti-malarial work of the Russian Health Service, and will take part in a conference on malaria. Leaving Russia on August 4th, the Commission will proceed to Italy to inspect the areas infected by malaria and to draw up a report on the results of the voyage. Throughout the journey the central health authorities of the countries visited have conducted the party and shown it both the actual conditions in the areas infected with malaria and the measures taken to instruct and organise the health service for combating this disease. The Commission will, therefore, be in a position to make an exhaustive report on the whole question of malaria in Southern and Eastern Europe. Prof. Nocht, Director of the Institute for Tropical Diseases in Hamburg, heads the Commission as vice-chairman, Great Britain, France, Italy, Spain, Roumania, Jugoslavia, and Russia also being represented.

University of London.—The Sharpey physiological scholarship, founded in memory of Prof. William Sharpey, will shortly be filled, on the recommendation of the Faculty of Medical Sciences of University College, London. The value of the scholarship is £160 a year. The scholar is provided with full opportunities for advancing the study of physiology and of undertaking research. He takes a small share in teaching and demonstrating to students. Applications, containing a full statement of candidates' educational record, including a list of publications, if any, should be sent to the secretary of University College, London (Gower-street, London, W.C. 1), not later than Saturday, July 26th.

Visit of American Medical Men to Great Britain.—Some 300 members of the Inter-State Post-Graduate Assembly will visit this country next year from June 1st to June 20th, and will be entertained at Liverpool, Leeds, Newcastle, Manchester, Glasgow, Belfast, and Dublin. and possibly at other places. During the visit the annual Congress of the Tri-State Medical Associations will be held under the presidency of Dr. W. J. Mayo, and the Royal Society of Medicine has placed at the disposal of the Congress some of its lecture rooms. There will be demonstrations at several of the large London hospitals. The visit will terminate by a trip to Paris. Local arrangements are in the hands of Sir Robert Jones, Sir Berkeley Moynihan. Sir William Milligan, Sir Harold Stiles, Sir William de Courcy Wheeler, Mr. Grey Turner, and Prof. Tuffier, of Paris, while the advisory committee in London will consist of Sir Humphry Rolleston, Sir William Hale-White, Sir StClair Thomson, Mr. H. J. Waring, and Mr. Philip Franklin, who is acting as the hon. secretary.

Royal Ear Hospital.—Mr. Geoffrey E. Duveen, chairman of the Royal Ear Hospital, Dean-street, Soho, London, W., announces that negotiations have now been completed for the purchase of a site on which to rebuild the hospital. This site is situated on the corner of Huntley-street and Pancras-street, Bloomsbury, W.C., and is adjacent to University College Hospital and the new Rockefeller buildings. The chairman, himself a victim of deafness, made it possible to commence this scheme by a gift of £15,000 to the hospital. The gift is a memorial to his father, the late Mr. Henry J. Duveen. The work of clearing the site and building the new hospital will be put in hand as soon as possible.

The late Dr. W. A. Evans.—The death occurred suddenly on July 7th of Dr. William Arnold Evans, of Oakworth, near Keithley, Yorks. Dr. Evans was found in a state of collapse in his surgery and died before medical aid could reach him. Dr. Evans qualified in 1883 as M.R.C.S. and L.S.A. In 1888 he took the M.D. of London University, in 1890 D.P.H. Camb., and B.Sc. Vict. in 1904. Before settling in practice in Bradford, he was for a time house physician in the Wolverhampton General Hospital, house physician at the Manchester Royal Infirmary, and resident at Monsall Fever Hospital. He was appointed medical officer of health for Bradford in 1891 and resigned this office in 1913, when he took up practice in Oakworth.

Star and Garter Home.—The King and Queen visited the Star and Garter Home for Disabled Sailors and Soldiers, Richmond, on July 10th, and were received by the Mayor of Richmond and others representing the borough. Lord Grenfell (the President), Sir Arthur Stanley and Sir William Bennett (chairman and vice-chairman of the governors), Lady Cowdray, Dame May Whitty, and Sir Edwin Cooper, the hon. architect, conducted their Majesties to the reception room, where Sir Arthur Stanley described the origin of the Star and Garter scheme, and expressed the thanks of the governors to the donors who had helped to build and endow the home, specially mentioning Sir Edwin Cooper, who had given his services free of charge. Dame May Whitty, chairman of the British Women's Hospital Committee, outlined the activities of that Committee in raising money for the building of the home from British women at home and abroad. The Queen received the deeds of the building from Lady Cowdray, the hon. treasurer of the British Women's Hospital Committee, and accepted a handsome album from Sir Edwin Cooper. A short religious ceremony was held, after which a number of presentations were made to their Majesties. including members of the British Red Cross Society and the Order of St. John of Jerusalem, and the following members of the hon. medical staff of the Star and Garter: Sir David Ferrier (consulting physician), Mr. Percy Sargent (consulting surgeon), and Mr. John Matthews (consulting bacteriologist). The King and Queen then made an extensive tour of the building, and spoke to some of the disabled soldiers before taking their departure.

Douglas, Isle of Man.—On July 8th the Manx legislature passed a vote for £20,000 from revenue to build a maternity ward for the island at Douglas Hospital. The cost of maintenance will be borne by the hospital committee.

North-East London Post-Graduate College.—An intensive course at the Prince of Wales's General Hospital will begin on July 21st and will last for 14 days. It will include lectures and demonstrations of clinical methods and cases, and work in the general wards and special departments of the hospital. Those proposing to take the course should send in their names to the Secretary of the Fellowship of Medicine, 1, Wimpole-street, W. 1, not later, if possible, than to-day, Friday, July 18th.

Manchester's Babies' Hospital.—In the view of the Public Health Committee this hospital is doing very good work, and a certain number of its beds are subsidised by the corporation and ear-marked for cases treated under the corporation's maternity and child welfare scheme. New wards to accommodate 80 patients are to be erected, and the Ministry of Health has already promised the grant of £6000, which will cover about one-half of the estimated cost of the new building. The corporation proposes to borrow £6000 and lend it to the board of management of the hospital. The board hopes to obtain £6000 by public subscription.

Bristol Medical Students' Visit to Bath.—A large party of medical students from Bristol University visited the bathing establishment on July 11th, under the auspices of Dr. J. Odery Symes, to extend their knowledge of medical hydrology and study its practical application as carried out by means of the exceptionally complete installation at the hot mineral baths of Bath. They were received by Mr. John Hatton, the director of the baths, and after going over the establishment and seeing various demonstrations, heard a lecture from Dr. Vincent Coates on the types of diseases chiefly treated at Bath. After tea the party visited the Roman baths.

The late Dr. J. H. Mawson.—On the night of July 10th Dr. James Hargreave Mawson, L.R.C.P. & S. Edin., of Leeds, sustained a fatal injury while riding his motorcycle. He was conveyed to the Leeds Infirmary where he died shortly after admission. Dr. Mawson graduated in 1882 and had an extensive practice in the city and was a well-known member of the Leeds Medical Panel Committee under the Health Insurance Acts. He was of a retiring disposition and took little part in active public life, but he was held in high esteem by his fellow practitioners and was regarded as a valued and most useful member of the panel committee.

Spanish Doctors in London.—A party of medical men from Spain arrived on July 17th on a visit to London, and have been accommodated at the Hotel Bedford, Southampton-row, W.C. They include Prof. Rafael Pizá, Prof. Ricardo Moragas, Dr. Domingo Duran Arrom, Dr. José Ma. Rosell, Dr. Luis de March, Dr. Juan San Ricart, Dr. Luis Vila Avadal, Dr. Francisco Humedas, Dr. Juan Sana, Prof. Domingo Carles, Mr. Arturo Claveria, Dr. Manuel Casanovas Camps, Mr. Pedro Casa Abarca, Dr. Pla y Armengol, Mr. Augustin Mestre. During the course of their visit lectures will be delivered in French by Dr. José Ma. Rosell on the Problem of the Intestinal Fermentations and Putrefactions, and by Dr. Pla y Armengol on the Bacteria of Tuberculosis; Dr. Armengol will also lecture in English on the Clinical Idea of Tuberculosis. As we go to press the date and place of these lectures are not settled.

Medicated Water.—At the Conference of the British Waterworks Association held recently, Sir Alexander Houston, director of water examination to the Metropolitan Water Board, read a paper on Purification of Water-supplies. Sheffield, he said, was the first place to adopt the lime treatment of moorland water, in order to correct the acidity, harden the water, and prevent its solvent action on lead. The use of rain-water for drinking purposes should be encouraged. At the present time, he said, a remarkable physiological experiment on a large scale was being carried out at Rochester, United States, which had given rise to the Derbyshire suggestion of medicating the water-supplies at Chesterfield for the purpose of arresting goitre or "Derbyshire neck." Small doses of a salt of iodine were being artificially added to the water-supply bi-annually for two or three weeks at a time with the object of preventing thyroidism. Although it was contrary to ordinary medical teaching to force a whole population to drink treated water for the benefit of the minority, Switzerland had shown some precedent for the experiment. A majority of persons would probably consider that these matters were best left in the hands of family doctors or medical officers of schools, and that it was outside the province of a waterworks authority to administer preventive drugs wholesale even in harmless doses.

The Oxford Press Library.—The library at the new home of the Oxford University Press in Warwick-square, London, E.C., is now open, and all interested in books are at liberty to inspect therein at their leisure any of the volumes, which number some 10,000. There is a librarian in charge, who is ready to supply information or give advice.

Donations and Bequests.—Among other legacies received during the past three weeks by the Edinburgh Royal Infirmary is one by Miss Jessie Aitken of Glenbervie, Larbert—sum to account of residue—£20,000 (permanent capital).—Sir Mortimer Singer has sent a cheque for £1000 to the Mayor of Torbay as a contribution to the Mayor's appeal for £80,000.—Among recent gifts to the British Red Cross Society for the British Empire Cancer Campaign is one of £3000 from an anonymous donor. The Staffordshire branch of the British Red Cross Society has sent £567, the Cheshire branch £240, and the Essex branch £204.—Dr. John Mallet Purser has offered to the Board of Trinity College, Dublin, where he is Regius Professor of Physics, £10,000 for the benefit of the school of physic and the schools of experimental and natural science.—The late Mr. John George Kincaid, of Greenock, left by will £1000 to the Greenock Royal Infirmary; £500 to the Greenock Eye Infirmary; and £500 to the Grenock District Nursing Association.—Under the will of the late Sir John Stewart Clark, Bart., the testator left £1000 to the Annie Clark Fund for Incurables, Paisley; £1000 to the Royal Alexandra Infirmary, Paisley; £1000 to the Royal Infirmary, Edinburgh; £500 to the Royal Victoria Eye Infirmary, Paisley; £500 to the Paisley Convalescent Home, West Kilbride; £500 to the Royal Edinburgh Hospital for Sick Children; and £500 to the Queen Victoria Jubilee Institute for Nurses, Edinburgh.—Mr. James Manfield, J.P., the head of Manfield and Sons, Limited, boot manufacturers, of Northampton, has given Weston Favell House, which he built about 25 years ago at a cost of over £100,000, to the Northampton Crippled Children's Fund for an orthopædic hospital. The house contains 23 bedrooms.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, July 21st, to Saturday, July 26th.—Prince of Wales's General Hospital, Tottenham. Special Intensive Course in Medicine and Surgery (first week). —Royal Eye Hospital, Southwark, S.E. Mon., 10.30 A.M., Mr. A. D. Griffith: Operations. Tues., 3 P.M., Mr. L. V. Cargill: Lecture-Dem. on Operations. 5 P.M., Dr. J. Collier: Ocular Paralyses. Wed., 3 P.M., Clinical Cases. 5 P.M., Mr. A. D. Griffith: Cataract. Thurs., 3 P.M., Clinical Cases. 5 P.M., Mr. W. J. Lindsay: Eye Complications in Acute Fevers. Fri., 3 P.M., Clinical Cases. 5 P.M., Mr. E. A. Dorrell: The Pupil in Diseases of the Eye.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, July 21st.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. Simson: Diseases of Women.

Tuesday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Wednesday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Medical Registrar: Clinical Methods. 2 P.M., Surgical Registrar: Surgical Out-patients.

Friday.—10 A.M., Mr. Dudley Buxton: Dental Dept. 11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Appointments.

Brunton, C. E., M.B. Camb., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Lyndhurst District of the County of Southampton.

Clark, G. A., M.D. Durh., Lectureship in Physiology at the University of Sheffield.

Dunscombe, Clement, M.B., B.Ch. Camb., D.P.H., Assistant County Medical Officer of Health and Assistant School Medical Inspector for Wiltshire.

Elvins, R. S., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Police Surgeon at Scarborough.

Fagan, R. F., M.B., B.S., D.P.H., Pathologist to St. John's Hospital for Diseases of the Skin.

McAlpine, Douglas, M.B., Ch.B. Glasg., M.R.C.P. Lond., Physician to the Department for Nervous Diseases at the Middlesex Hospital.

Scott, Evelyn M., M.B., B.S. Durh., Junior Resident Medical Officer, Royal Infirmary, Sunderland, to act as House Physician at the Children's Hospital.

Queen Charlotte's Maternity Hospital: Banister, J. Bright, M.D. Camb., F.R.C.S. Edin., Consulting Obstetric Surgeon; Rivett, L. C., M.C. Camb., F.R.C.S. Eng., Obstetric Surgeon to In-patients; Lane-Roberts, C. S., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon to Out-patients; Jones, A. Morris, M.B., Ch.B., Senior Resident Medical Officer; Cargill, R. E. D., M.R.C.S., L.R.C.P. Lond., and Robertson, J. A. W., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officers.

University of Edinburgh: Lyon, D. Murray, M.D., D.Sc. Edin., F.R.C.P. Edin., D.P.H., F.R.S. Edin., Christison Professor of Therapeutics, in succession to Prof. J. C. Meakins; Greig, Lt.-Col. E. D. W., I.M.S., M.D., D.Sc., Lecturer in Tropical Diseases.

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. £130.

Birmingham City Municipal Bacteriological Laboratory.—Asst. Bacteriologist and Asst. Venereal Diseases Officer. £600.

Birmingham Cripples' Union Orthopædic Hospital.—H.S. £250.

Birmingham, Rubery Hill and Hollymoor Mental Hospital, Northfield.—Asst. M.O. £350.

Brentwood Mental Hospital.—Jun. Asst. M.O. £510.

Brighton County Borough Sanatorium.—Res. M.O. £350.

Brighton Education Committee.—Junior School Dentist. £400.

Cambridge, Addenbrooke's Hosp.—Cas. O. and Res. Anæsth. £130.

Cardiff City.—Res. Med. Supt. and Asst. M.O.H. £700.

Derby County Mental Hospital, Mickleover.—Sen. Asst. M.O. £450. Also Locum Tenens M.O. £8 8s. per week.

Evelina Hospital for Children.—H.S. and H.P. £120 each.

Freemasons Hospital and Nursing Home.—Res. M.O. £250.

Gloucestershire Royal Infirmary, Gloucester.—P.

Hull Royal Infirmary.—Asst. H.P. £130.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Lincoln County Hospital.—Jun. H.S. £150.

Liverpool City.—M.O.H. £1800.

London Temperance Hospital.—Cas. O. £150.

Manchester Royal Infirmary, Barnes Convalescent Hospital, Cheadle.—Res. M.O. £250.

Margate, Royal Sea Bathing Hospital.—H.S. £200.

Middlesex County Council Sanatorium, Harefield.—Locum M.O. £7 per week.

North Middlesex Hospital, Edmonton.—Asst. M.O. £200.

Oldham County Borough.—Asst. M.O.H. £450.

Queen's Hospital for Children, Hackney, E.—Asst. S. to Ear, Nose, and Throat Dept.

Rochdale Infirmary.—M.O. 300 guineas.

Salford Royal Hospital.—Hon. Asst. S.

Seamen's Hospital Society.—S.

Sheffield Royal Infirmary.—Med. Reg. £400. Ophthalmic H.S. £60. Also Asst. S.

Sudan Medical Service.—Medical Inspector. L.E.720.

University College Hospital, Gower-street, W.C.—Non.-Res. House Anæsth. £100.

Ventnor, Royal National Hospital for Consumption, &c.—Sen. Res. M.O. £300.

Willesden General Hospital.—Hon. S.

Births, Marriages, and Deaths.

BIRTHS.

Chapman.—On July 10th, at The Green, Richmond, Surrey, the wife of Capt. R. W. Chapman, R.A.M.C., of a son.

MARRIAGES.

Henderson—Hunter.—On July 12th, at St. Stephen's Parish Church, Perth, Alan Ashton Henderson, M.R.C.S., L.R.C.P., of Golders Green, London, to Dorothy Margaret, youngest daughter of Robert Hunter, of St. John's, Perth, Scotland.

Wilson—Snell.—On July 3rd, at the Parish Church, Kilmington, Devon, Edric Frank Wilson, F.R.C.S. Eng., of Plymouth, son of Mr. and Mrs. F. Wilson, of Acton, Middlesex, to Vera, younger daughter of Mr. and Mrs. R. Snell, of Kilmington.

DEATHS.

Collins.—On July 11th, at "The Mall," Wanstead. Essex, George William Collins, L.R.C.P. Lond., M.R.C.S. Eng.

Mawson.—On July 10th, as the result of an accident, James Hargreave Mawson, L.R.C.P., L.R.C.S., of Moorland-road, Leeds, in his 66th year.

Russell-Wells.—On July 14th, in his 55th year, Sir Sydney Russell-Wells, M.P., M.D. Lond., F.R.C.P. Lond.

Saunders.—On July 7th, Henry William Saunders, M.D., F.R.C.S., of Eastbourne.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

AN IMPROVED METHOD FOR ARTIFICIAL RESPIRATION.

By Dr. Edwin Seaborn.

For some time I have been accustomed to practise a method of artificial respiration which has proved itself in my hands quite useful. I have reviewed medical literature with the object of ascertaining how far the method is original. I shall therefore give a brief account of the methods hitherto recommended before describing that which I have devised.

Methods of Artificial Respiration.

The methods hitherto in use may be classified as follows: (1) Those which either expand or compress the chest to such an extent that air enters the lungs; (2) those in which air, under pressure, is forced into the lungs.

Included in the first class are those of:—

(*a*) Leroy. As the patient lies on his back, pressure is applied to the abdominal wall. On relaxing the pressure the natural recoil of the body allows air to enter the lungs, the inspiration being chiefly of the abdominal type.

(*b*) Howard. The patient lies on his back with a cushion under his shoulders, and strong pressure is applied to the lower chest and abdomen. The recoil of the chest on relaxing the pressure produces inspiration again of an abdominal type.

(*c*) Sylvester. As the patient lies on his back his arms are first pulled strongly over his head. Traction on the chest, through the pectoral muscles, produces inspiration. In the next movement the arms are pressed against the side of the chest, so assisting expiration.

(*d*) Brosch. This method resembles Sylvester's. The arms, after being brought over the head, are pressed while still in this position downwards until the thorax is raised by this leverage from the table. The force applied passes to the chest through the pectoral muscles and through the ligaments of the shoulder-joints to the scapulæ, so expanding and raising the chest and producing inspiration. Expiration is assisted by pressing the arms against the sides of the chest.

(*e*) Shücking. This method also resembles Sylvester's. The arms are pulled laterally from the sides of the body to a point above the head. The latissimus dorsi as well as the pectoral muscles are utilised to expand the chest, and so to produce inspiration. Expiration is assisted by pressing the arms against the sides of the chest.

(*f*) Marshall Hall. The patient lying on his side is allowed to sink face downwards until the front of the chest and abdomen are nearly in contact with the table, thus expelling air. In the next movement he is pulled up by the upper shoulder and hip. The force thus applied passes through the pectoral muscles of the upper shoulder to the chest and so produces inspiration.

(*g*) Francis. While the patient lies on his back, the body is alternatively raised and lowered by a pole thrust across under the chest. When the body is raised, the head and shoulders draw upon the chest through the pectoral and neck muscles, so producing inspiration.

(*h*) Schüller. The patient lies on his back, and the operator's fingers are hooked under the costal margins. Traction in an upward direction is then applied, expanding the chest, so producing inspiration.

(*i*) Pacini. While the patient lies on his back with the feet tied to the table, his shoulders are alternately pulled upward and pushed downwards, so producing inspiration and expiration. The force applied passes to the chest through the pectoral and latissimus dorsi muscles.

(*j*) Schroeder (for infants). The child, face upwards, is placed across the operator's hands. To produce expiration the child's body is flexed, approximating its head and feet. To induce inspiration its head and feet are allowed to hang over the edge of the operator's hands. The head and shoulders draw on the chest through the pectoral and neck muscles.

(*k*) Buist (for infants) is much like Schroeder's. The child, face downwards and with the head away from the operator, is held on one of the operator's hands. It is rolled over into the other hand. The child is now face upwards with the head hanging down, and inspiration takes place. The head and shoulders draw on the chest, through the pectoral and neck muscles, so producing inspiration.

(*l*) Schäfer. While the patient lies on his face, strong pressure is applied to the lower part of the thorax. The cubic content of the chest is reduced much below that of even forced expiration. The natural recoil of the chest on relaxing the pressure produces inspiration.

In all the above methods except those of Leroy, Howard, and Schäfer, the expansion of the chest in inspiration depends very largely on traction applied through the pectoral muscles. Unfortunately, in the conditions which render recourse to artificial respiration necessary, the pectoral, like all the other voluntary muscles, have lost their tone, and a large part of the force applied is uselessly expended on the shoulder-joints instead of on the chest.

Of the many methods of the second class—i.e., in which air is *forced into the lungs*—the following are the chief :—

(*m*) The founders of the Royal Humane Society who adopted in 1774 the method utilised by the Dutch Society. The *mouth of the operator is applied to the mouth of the* patient, and the latter's lungs are inflated by blowing. The idea of mouth-to-mouth inflation is probably as old as the idea of resuscitation itself.

(*n*) John Hunter (1776) used a bellows, with double cylinders, which takes the place of the operator's mouth. Air is alternately injected and withdrawn. The ordinary fireside bellows had already been used for centuries for resuscitation.

(*o*) Kite used an apparatus which inflated and deflated the lungs, and his method was adopted by the Royal Society in 1786.

(*p*) Munro employed a catheter which was passed into the larynx, and was attached to a bellows.

Sir Benjamin Brodie, who had been requested to investigate the methods employed in resuscitation, reported against the use of bellows, and their employment was accordingly discontinued during many years thereafter.

(*q*) Hovatch placed the nozzle of a bellows in one nostril, and, while the mouth and other nostril were held closed, air was alternately forced into and withdrawn from the lungs.

(*r*) Stewart and Rogoff placed the nozzle of a bellows in the mouth, and while the nostrils were held closed, alternately forced air into and withdrew it from the lungs. The pressure of air was regulated by a valve.

(*s*) Sir Lauder Brunton, at the International Congress held at Rome in 1894, exhibited an apparatus which utilised an oxygen tank. A nozzle was placed in each nostril.

One disadvantage of all the methods by which air is forced into the mouth, nose, or pharynx is that air enters the stomach and pushes the diaphragm upwards, so diminishing the capacity of the chest. Many means have been suggested for obviating this, and among these are the following :—

(*t*) Roth, in using a bellows and a tightly fitting face-mask, at the same time applied pressure to the œsophagus.

(*u*) Kuhn used an instrument consisting of an inner and outer tube, which was pushed through the larynx, completely filling the glottis. Through the inner tube, a continuous stream of air was forced into the lungs, while through the space between the inner and outer tubes the air as constantly escaped. Just sufficient air pressure as would keep the lungs distended was employed.

(*v*) O'Dwyer and Fell employed an apparatus which very much resembles Kuhn's. It consisted of a double laryngeal tube. By alternately opening and closing the outgoing tube the chest was made to move as in ordinary respiration.

In 1908 Volhard demonstrated that an animal whose muscles had been paralysed by curare could be kept alive by injecting a stream of air into the trachea. He showed also that oxygen is more effective than air.

In 1909 Meltzer and Auer described a method of *inducing anæsthesia* by passing a stream of etherised air through a catheter passed into the trachea as far as the bifurcation of the trachea. At a pressure of 20 to 25 mm. of mercury anæsthesia could be continued indefinitely although no respiratory movements of the chest took place. The catheter employed must be of such calibre as to give space for the return of air from the lungs, otherwise cyanosis occurs. The cyanosis, however, disappears if the stream of ingoing air is stopped for a few seconds. Meltzer and Auer suggested that the apparatus would be of service for the resuscitation of the drowned.

In 1912 the American Medical Association, in coöperation with the National Electric Light Association and the Association of Electrical Engineers, inquired into the means and devices employed for resuscitation. In 1914 the American Government requested the American Medical Association to recommend the apparatus which, in their opinion, would be the most serviceable for use by laymen in emergencies.

American Medical Association's Report and Suggested Method.

The Association named a committee consisting of Dr. G. W. Crile; Dr. Meltzer, of the Rockefeller Institute; W. B. Cannon, of Howard University; James Erlanger, of Washington University; and Yandell Henderson, of Yale. After exhaustive investigations, carried out on animals and man, they reported that existing devices were either mechanically uncertain or that they injured the lungs by withdrawing air under negative pressure. They recommended the use of a new method based on that of Meltzer and Auer already described.

In this modification a suitable metal tube, several sizes of which must be kept on hand, is passed into the pharynx, and a *glass-blower's bellows* is employed to pump air into the lungs. The air-pressure is regulated at 20 to 30 mm. Hg by means of a valve. A heavy weight, secured by a broad bandage, is placed on the belly, or a man is made to sit on the abdomen. The flow of air is interrupted by a valve worked by the hand, so causing inspiration and expiration alternately.

Regarding the physiology of respiration, I would point out *that the hæmoglobin of the aerated blood of the lungs always* carries a full load of oxygen. When more oxygen is needed an increase is effected by a combination of two factors: (1) *by increasing the rapidity of the flow of blood through* the lungs; and (2) by increasing the rate and depth of respiration. The increase of the depth of respiration effects an increase in the surface of lung epithelium exposed to the air. In asphyxia we can control the second factor only, and that by artificial respiration. To compensate for the feebleness of the circulation the aerating surface, and therefore *the air content of the lungs, should be increased to its* maximum.

Technique of the New Method.

The method which I have devised, and shall now describe, seems to be particularly adapted *to* achieve this result.

As we have seen, most of the methods depend upon indirect traction on the pectoral muscles. The new method depends upon traction applied directly to these same muscles, the toneless condition of which now aids in the procedure.

A man stands on each side of the patient, each with palms held upwards; each grasps very firmly with both hands the anterior axillary folds. The hand which is nearer to the patient's head passes deeply into the axilla and takes a broad hold of the pectoralis major and minor muscles. The other hand grasps the anterior axillary fold as low on the chest as possible, so taking hold of the lower part of the origin of the pectoralis major muscle. Traction is then applied in both an upward and outward direction until the thorax is lifted from the table, and until the lower part of the latter is expanded to its greatest extent. A long blast of air is heard to whistle through the larynx. This whistling continues for several seconds. It is most important that traction be continued until the whistling ceases, as otherwise the area of lung inflated with air does not arrive at its maximum. In this method both the upper and lower thorax are fully expanded. It would appear that the diaphragm descends and, owing to the lateral traction, is pulled out flat. To aid expiration pressure is applied through the operator's hands to the chest-wall, but the grasp on the axillary folds need not, during this movement, be relaxed. These movements are performed alternately. Where two men are not available this method of practising artificial respiration can be carried out by one operator standing at the patient's head. The best results, however, cannot be obtained in this way, as the lateral pull outwards cannot be applied with the same force. The method is not one exclusively for the operating-table, but may equally well be applied in the case of the apparently drowned, after clearing as far as possible the air-passages of water or other substances.

Advantages of the New Method.

The author in several cases of asphyxia has had the opportunity of comparing this method with those of the first class already described. From the intensity and duration of the whistling in the larynx it becomes immediately apparent that the amount of air which enters the lungs at each respiration is very much greater than in any of these other methods.

With a view to measuring the volume of air which enters and leaves the lungs with each respiration, experiments were conducted on the cadaver in the pathological department of St. George's Hospital, and with the assistance of Dr. Robert Donaldson, head of that department.

In all the methods of the first class very little air entered or left the lungs. In no case was there a flow of more than a few cubic centimetres, so few, indeed, that the amount could not be conveniently measured in the spirometer employed. In the method which I advocate there was constantly, with each movement, a flow of 200 cubic centimetres of air.

I believe that the method is superior to all others because of the greater air-intake, because it can be applied at once, because of its extreme ease of application, because no apparatus is necessary, and because it can be applied with little risk of sepsis during an abdominal operation. It should be applied *immediately* after the patient's respirations fail.

I would suggest that a funnel attached to an oxygen tank be placed close to the patient's mouth. I would further suggest that pressure be put on the abdominal aorta and inferior vena cava, and on the brachial arteries and veins so that the blood may be determined to the brain and respiratory centres. These centres are very rapidly and profoundly damaged by lack of oxygen, so profoundly, indeed, that they may be unable to recover even though the heart-beats may for a time increase in rate and power.

Notes, Comments, and Abstracts.

AN IMPROVED METHOD FOR ARTIFICIAL RESPIRATION.

By Dr. Edwin Seaborn.

For some time I have been accustomed to practise a method of artificial respiration which has proved itself in my hands quite useful. I have reviewed medical literature with the object of ascertaining how far the method is original. I shall therefore give a brief account of the methods hitherto recommended before describing that which I have devised.

Methods of Artificial Respiration.

The methods hitherto in use may be classified as follows: (1) Those which either expand or compress the chest to such an extent that air enters the lungs; (2) those in which air, under pressure, is forced into the lungs.

Included in the first class are those of:—

(*a*) Leroy. As the patient lies on his back, pressure is applied to the abdominal wall. On relaxing the pressure the natural recoil of the body allows air to enter the lungs, the inspiration being chiefly of the abdominal type.

(*b*) Howard. The patient lies on his back with a cushion under his shoulders, and strong pressure is applied to the lower chest and abdomen. The recoil of the chest on relaxing the pressure produces inspiration again of an abdominal type.

(*c*) Sylvester. As the patient lies on his back his arms are first pulled strongly over his head. Traction on the chest, through the pectoral muscles, produces inspiration. In the next movement the arms are pressed against the side of the chest, so assisting expiration.

(*d*) Brosch. This method resembles Sylvester's. The arms, after being brought over the head, are pressed while still in this position downwards until the thorax is raised by this leverage from the table. The force applied passes to the chest through the pectoral muscles and through the ligaments of the shoulder-joints to the scapulæ, so expanding and raising the chest and producing inspiration. Expiration is assisted by pressing the arms against the sides of the chest.

(*e*) Shücking. This method also resembles Sylvester's. The arms are pulled laterally from the sides of the body to a point above the head. The latissimus dorsi as well as the pectoral muscles are utilised to expand the chest, and so to produce inspiration. Expiration is assisted by pressing the arms against the sides of the chest.

(*f*) Marshall Hall. The patient lying on his side is allowed to sink face downwards until the front of the chest and abdomen are nearly in contact with the table, thus expelling air. In the next movement he is pulled up by the upper shoulder and hip. The force thus applied passes through the pectoral muscles of the upper shoulder to the chest and so produces inspiration.

(*g*) Francis. While the patient lies on his back, the body is alternatively raised and lowered by a pole thrust across under the chest. When the body is raised, the head and shoulders draw upon the chest through the pectoral and neck muscles, so producing inspiration.

(*h*) Schüller. The patient lies on his back, and the operator's fingers are hooked under the costal margins. Traction in an upward direction is then applied, expanding the chest, so producing inspiration.

(*i*) Pacini. While the patient lies on his back with the feet tied to the table, his shoulders are alternately pulled upward and pushed downwards, so producing inspiration and expiration. The force applied passes to the chest through the pectoral and latissimus dorsi muscles.

(*j*) Schroeder (for infants). The child, face upwards, is placed across the operator's hands. To produce expiration the child's body is flexed, approximating its head and feet. To induce inspiration its head and feet are allowed to hang over the edge of the operator's hands. The head and shoulders draw on the chest through the pectoral and neck muscles.

(*k*) Buist (for infants) is much like Schroeder's. The child, face downwards and with the head away from the operator, is held on one of the operator's hands. It is rolled over into the other hand. The child is now face upwards with the head hanging down, and inspiration takes place. The head and shoulders draw on the chest, through the pectoral and neck muscles, so producing inspiration.

(*l*) Schäfer. While the patient lies on his face, strong pressure is applied to the lower part of the thorax. The cubic content of the chest is reduced much below that of even forced expiration. The natural recoil of the chest on relaxing the pressure produces inspiration.

An Address

ON

YESTERDAY, TO-DAY, AND TO-MORROW.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association in Bradford on July 22nd, 1924,

By J. BASIL HALL, M.A., M.Ch. Camb.,
HONORARY CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY.

My Lord Bishop, Ladies and Gentlemen,—As a Bradford citizen, my first words must be those of a very warm welcome to the British Medical Association. As the President of that Association, on the other hand, I can truly say that I, and every other member of it, have greatly appreciated the very cordial and hospitable reception which the citizens of Bradford have given to us. Although our Association has existed for upwards of 90 years without visiting this city, I can assure you that it was recognised long ago that Bradford had only to be asked and a generous response would be forthcoming.

There is an incident in the history of this city which coincides with the birth of the British Medical Association. In 1832 the Association came into being, and almost simultaneously the town of Bradford was granted the privilege of returning two Members of Parliament. Whether this privilege proved a boon to the city or otherwise I do not know, because I am ignorant of the political views which those Members held. I can only say that I hope they coincided with my own. As regards the birth of the British Medical Association, however, I have no doubts. That great body has done an unspeakable service in binding together the great mass of the medical profession into one solid professional unity. At its inauguration in Worcester by Sir Charles Hastings some 50 original members were enrolled. To-day its membership numbers 27,000 members, scattered over the whole world, and it can justly claim that its voice is the voice of a profession throughout an empire upon which the sun never sets.

I am not going to weary you by recording all that this great Association has accomplished during its long existence, but I cannot refrain from mentioning what I regard as its greatest achievement. When war broke out in 1914 our army was served by the Royal Army Medical Corps. That is a very small body, large enough to give medical service to our soldiers in times of peace, but totally inadequate to meet the requirements of a great war. The British Medical Association promptly established a central war committee and through it provided for our army a regular and organised supply of medical officers throughout the whole campaign. The cost of that patriotic service amounted to £20,000, and it is the proud boast of this country to-day that the care of the sick and wounded has never been equalled in the previous history of the world. If the Association had never done anything else, its war record has more than justified its existence.

Before proceeding further I want to express my very sincere thanks for the loyal and unstinted help which has been so generously given in order that this meeting, the first of its kind in Bradford, should prove a success. When I look back upon the past 12 months and try to realise all the generous service which has been so willingly rendered, I feel that I cannot adequately express my thanks. To name some and omit others would appear invidious, but I must mention our Lord Mayor and others who represent the corporation of this city; and I would especially thank the ladies' committees who have done such yeoman service. Even in the Garden of Eden Adam was a failure till Eve came along, and although she let him down very badly to begin with, she has since earned his eternal gratitude, and we recognise to-day that without her coöperation our annual meetings must prove a failure.

A gathering like this is not merely a national conference. It is something which knits together a professional brotherhood which extends throughout the world. It brings together representatives from all parts of the British Isles, from our overseas dominions, and from the great contingents of Europe and America. It accepts representatives of all those who work with a common object from nations outside our Empire, and it welcomes them as members of a great medical fraternity. There is no such word as "foreign" in the world of medicine. Politicians talk about a League of Nations, but in medicine nations count as nothing. The fight against disease is carried on wherever the human race exists, and we recognise that each does his best according to the knowledge vouchsafed to him. I was told recently that Bradford had no medical traditions and its reputation had still to be made. I accepted the insult with equanimity because I felt I was in the company of several to whom I could bow the knee without humiliation. My mind went back to Dr. Sharpe and to the first Dr. Meade, both Fellows of the Royal Society; and then to the late Dr. John Bell, Dr. Goyder, and others who demonstrated that woolsorters' disease was due to the anthrax bacillus. Also to the late Sir Thomas Stephenson, who became adviser to the Home Office in medical jurisprudence, and who, by his expert evidence, brought many criminals to justice. Then to the most kind-hearted little man I ever knew, the late Dr. Major, an expert in mental disease, one whose whole desire in life was to help everybody. In later days there remains with us the memory of Dr. James Kerr, who left Bradford to become the medical officer of the London School Board—a brilliant scholar, who never realised how brilliant he was even when it was impressed upon him by others. Perhaps I ought not to say anything about those who still remain with us, but I am tempted to express my admiration for the long and patient work which has been given to the effort to discover a sure means of disinfection of wool without destroying its commercial value, and I hope that this will one day obtain success and a well-deserved recognition.

Bradford is essentially a commercial centre, and its citizens respect everyone who advances commercial prosperity. They are enthusiastic in promoting education which has a practical and not merely an academic value. Nevertheless, it is a curious fact, if history be true, that the city owes much of its prosperity to a clergyman. The invention of the power loom emanated from Dr. Cartwright, a Fellow of Magdalen College, Oxford, afterwards incumbent of Brampton in Yorkshire and Prebendary of Lincoln Cathedral. Incidentally, he married an heiress and perhaps she, too, did much to make that invention possible. Thanks to the late Lord Masham's father, his memory is perpetuated by the Cartwright Memorial Hall in Lister Park.

My predecessor has handed on to me the difficult task of delivering a presidential address, and my only comfort is that you will not be allowed to express any criticisms upon my efforts. Reflections on the past and prophecies about the future are time-honoured but very hackneyed topics, but I am going to say something to-night about "The Yesterday, the To-day, and the To-morrow" of medicine.

I think that we are tending to lose our veneration for the past: perhaps we are too conceited about our present, and expect too much of the future. It is only human nature when most of us smile superciliously at the lack of scientific knowledge of our early medical ancestors and fail to appreciate the magnificent courage and perseverance with which they fought a losing battle against disease. Rudyard Kipling accurately described our modern mental attitude when he wrote:—

> "Wonderful little, when all is said,
> Wonderful little, our fathers knew,
> Half their remedies cured you dead,
> Most of their teaching was quite untrue."

PUBLIC HEALTH IN CAPE TOWN.

WE have received from Dr. T. Shadick Higgins the annual health report of Cape Town for the year ended June 30th, 1923. Dr. Higgins only took over the duties on June 18th, 1923, so that the period dealt with shows the health position at the beginning of his term of office. It may therefore be of interest to give a table showing some of the principal health statistics for the European and non-European populations respectively, for comparison with English districts.

Race.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Diseases respiratory system.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
European . ..	107,430	22·3	11·1	0·7	0·9	1·4	30	82	4·6
Non-European .	83,590	51·5	29·2	4·2	0·5	8·1	50	200	4·6

It will be noted that the statistics of the European population of Cape Town do not differ appreciably from those of a clean-aired English town, while the non-European population has a very high birth-rate and an excessive death-rate from all causes, tuberculosis and respiratory diseases, the death-rate from cancer being low and the maternity mortality from childbirth being equal to that of the Europeans. Dr. Higgins, in presenting the report, pays a tribute to the good work of his predecessor, Dr. A. Jasper Anderson, the first whole-time medical officer of health for the city, who gave up his appointment on March 31st, 1923, after over 21 years' service.

A study of the report makes it obvious that public health problems in Cape Town are not essentially different from those in the old country. Thus, among the admissions to the City Hospital for Infectious Diseases, the only unusual ailments are one fatal case of anthrax, and one case of Malta fever which recovered. Enteric fever heads the list numerically, as might have happened in an English hospital during the 'eighties of last century. In the table giving the causes of death, the most striking features are the prominence of enteric fever among both races, and of diarrhœa, disease of the stomach, enteritis, syphilis, bronchitis, and pneumonia amongst the non-European population. During the year seven cases of leprosy were notified, one European female and three each of non-European males and females. There were no deaths from leprosy recorded. An outbreak of influenza occurred during June, 1922, and continued into the year under review, and was accountable for seven European and five non-European deaths. As in many parts of England, a small-pox hospital serves the purpose of many surrounding districts. The report of the maternity and child welfare work, submitted by Dr. Mary van Ingen, shows that this department is administered on similar lines to those at home. There are ten sanitary inspectresses and a chief. The notification of every child born after the completion of the sixth month of pregnancy, whether alive or dead, is required within 24 hours. Of 7088 births notified during the year, 6337 were notified by midwives and nurses, 740 by parents and others, and 11 by doctors. Five bureaus for infant consultations are in operation, and their work continues to increase. Voluntary workers give their help. Minor ailments are treated at the bureaus, dried mild is supplied to infants who cannot be breast-fed, and free dinners are provided at two centres for poor nursing mothers. A sanatorium is needed for tuberculosis, as the accommodation in the infectious diseases hospital is inadequate. Last year 100 cases were admitted to the last-named hospital. Dr. W. P. Cooney, in his report as to the work of the male V.D. centre, emphasises the need for education of the public, and points out that suitably trained coloured and native lecturers would do an immense amount of good in this direction.

As examples of the prevalence of venereal disease in Cape Town, he mentions one household where three servants out of five were suffering from syphilis, one being in an infectious state, and a public institution in which four members of the staff were sufferers, two of whom, one infectious, were concerned with food preparation. The want of proper homes, lack of education, and the almost complete absence of moral sense in a number of patients attending the clinic are some of the difficulties. One of the greatest dangers is supplied by the large floating population of the casual type who sleep in the open and cannot be induced to attend for regular treatment. In spite of these difficulties only one case of "accidentally acquired" syphilis was noted during the past year. One definite case of reinfection of syphilis was also noted. In her account of the female V.D. clinic, Dr. Mary van Ingen shows that 64 pregnant women were treated, and that of these 32 gave birth to healthy infants, 20 ceased to attend with results unknown, one infant was born with spina bifida and died at 17 days old, while the remaining five whose treatment was insufficient had stillbirths or infants who developed syphilis. Three of the last-mentioned five only came up for treatment during the last month of pregnancy.

New regulations for protecting the milk-supply were introduced in October, 1922, and follow lines which are familiar in this country. Attention is given to the protection of meat while on sale by the provision of fly- and dust-proof screens, and improvements have been made in the type of carts and wagons used in the conveyance of meat. During the summer months two men are constantly employed in dealing with the mosquito and fly nuisance. Two deaths of Europeans from malaria were recorded during the year—one at the age-period 1 to 5, and the other at the age-period 35 to 45.

A large amount of work has been done in repairing and improving insanitary property, but owing to the scarcity of houses the council has been holding its hand with regard to closing of houses.

JUNKET POWDER.

Messrs. Edward Birks and Son, 88, Castle-street, Reading, have submitted to us a sample of junket powder which consists of active rennet in a desiccated form. Our tests have shown that junket made by its use possesses all the qualities of that made with liquid rennet, while the dry powder keeps its qualities unimpaired and has the additional advantage of being easily portable. Birks's junket powder is sold in bottles from 4½d. to 3s. 6d., and a small wooden measure is supplied with each bottle.

ARE WHITE CATS WITH BLUE EYES DEAF?

To the Editor of THE LANCET.

SIR,—There is an interesting article in the *Quarterly Journal of Medicine*, April, 1924, by Dr. Stobie, on the association of blue sclerotics with brittle bones and progressive deafness. I was not aware of the associated deafness till I read this recently. Long ago I read the statement—I rather think in one of Darwin's works—that white cats with blue eyes are always deaf. I have once or twice been able to verify this, though not recently, but I would suggest that the coincidence is sufficiently striking to make it worth while to follow up this interesting problem in comparative pathology to see whether the resemblance is more than superficial. I feel fairly sure that in one case the same features appeared in some of the kittens, but I did not look closely at the sclera or do more than satisfy myself as to the deafness.

I am, Sir, yours faithfully,
EDMUND HOBHOUSE.

Brechin-place, S.W., July 10th, 1924.

CLERGYMEN AND HOUSEMAID'S KNEE.

IN the recent Conjoint Examination a candidate, who had already given evidence of common sense as well as surgical acumen, was asked by one of the examining surgeons why clergymen did not suffer from housemaid's knee. The answer desired was that housemaids habitually strain to scrub or dust more ground when kneeling on one spot than they can conveniently reach, and therefore poise themselves on the patella with their heels in the air; whereas clergymen kneel decorously on the tuberosity of the tibia, almost sitting on their heels. This is an ingenious suggestion which might well form a subject of instruction for domestic workers.

Portable Radiographs.—The telephonic address of this firm at 1, Woodstock-road, Bedford Park, London, W. 4, on whose work we commented in last week's issue of THE LANCET, is *Chiswick 2162.*

An Address

ON

YESTERDAY, TO-DAY, AND TO-MORROW.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association in Bradford on July 22nd, 1924,

BY J. BASIL HALL, M.A., M.CH. CAMB.,
HONORARY CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY.

MY LORD BISHOP, LADIES AND GENTLEMEN,—As a Bradford citizen, my first words must be those of a very warm welcome to the British Medical Association. As the President of that Association, on the other hand, I can truly say that I, and every other member of it, have greatly appreciated the very cordial and hospitable reception which the citizens of Bradford have given to us. Although our Association has existed for upwards of 90 years without visiting this city, I can assure you that it was recognised long ago that Bradford had only to be asked and a generous response would be forthcoming.

There is an incident in the history of this city which coincides with the birth of the British Medical Association. In 1832 the Association came into being, and almost simultaneously the town of Bradford was granted the privilege of returning two Members of Parliament. Whether this privilege proved a boon to the city or otherwise I do not know, because I am ignorant of the political views which those Members held. I can only say that I hope they coincided with my own. As regards the birth of the British Medical Association, however, I have no doubts. That great body has done an unspeakable service in binding together the great mass of the medical profession into one solid professional unity. At its inauguration in Worcester by Sir Charles Hastings some 50 original members were enrolled. To-day its membership numbers 27,000 members, scattered over the whole world, and it can justly claim that its voice is the voice of a profession throughout an empire upon which the sun never sets.

I am not going to weary you by recording all that this great Association has accomplished during its long existence, but I cannot refrain from mentioning what I regard as its greatest achievement. When war broke out in 1914 our army was served by the Royal Army Medical Corps. That is a very small body, large enough to give medical service to our soldiers in times of peace, but totally inadequate to meet the requirements of a great war. The British Medical Association promptly established a central war committee and through it provided for our army a regular and organised supply of medical officers throughout the whole campaign. The cost of that patriotic service amounted to £20,000, and it is the proud boast of this country to-day that the care of the sick and wounded has never been equalled in the previous history of the world. If the Association had never done anything else, its war record has more than justified its existence.

Before proceeding further I want to express my very sincere thanks for the loyal and unstinted help which has been so generously given in order that this meeting, the first of its kind in Bradford, should prove a success. When I look back upon the past 12 months and try to realise all the generous service which has been so willingly rendered, I feel that I cannot adequately express my thanks. To name some and omit others would appear invidious, but I must mention our Lord Mayor and others who represent the corporation of this city; and I would especially thank the ladies' committees who have done such yeomen service. Even in the Garden of Eden Adam was a failure till Eve came along, and although she let him down very badly to begin with, she has since earned his eternal gratitude, and we recognise to-day that without her coöperation our annual meetings must prove a failure.

A gathering like this is not merely a national conference. It is something which knits together a professional brotherhood which extends throughout the world. It brings together representatives from all parts of the British Isles, from our overseas dominions, and from the great contingents of Europe and America. It accepts representatives of all those who work with a common object from nations outside our Empire, and it welcomes them as members of a great medical fraternity. There is no such word as "foreign" in the world of medicine. Politicians talk about a League of Nations, but in medicine nations count as nothing. The fight against disease is carried on wherever the human race exists, and we recognise that each does his best according to the knowledge vouchsafed to him. I was told recently that Bradford had no medical traditions and its reputation had still to be made. I accepted the insult with equanimity because I felt I was in the company of several to whom I could bow the knee without humiliation. My mind went back to Dr. Sharpe and to the first Dr. Meade, both Fellows of the Royal Society: and then to the late Dr. John Bell, Dr. Goyder, and others who demonstrated that woolsorters' disease was due to the anthrax bacillus. Also to the late Sir Thomas Stephenson, who became adviser to the Home Office in medical jurisprudence, and who, by his expert evidence, brought many criminals to justice. Then to the most kind-hearted little man I ever knew, the late Dr. Major, an expert in mental disease, one whose whole desire in life was to help everybody. In later days there remains with us the memory of Dr. James Kerr, who left Bradford to become the medical officer of the London School Board—a brilliant scholar, who never realised how brilliant he was even when it was impressed upon him by others. Perhaps I ought not to say anything about those who still remain with us, but I am tempted to express my admiration for the long and patient work which has been given to the effort to discover a sure means of disinfection of wool without destroying its commercial value, and I hope that this will one day obtain success and a well-deserved recognition.

Bradford is essentially a commercial centre, and its citizens respect everyone who advances commercial prosperity. They are enthusiastic in promoting education which has a practical and not merely an academic value. Nevertheless, it is a curious fact, if history be true, that the city owes much of its prosperity to a clergyman. The invention of the power loom emanated from Dr. Cartwright, a Fellow of Magdalen College, Oxford, afterwards incumbent of Brampton in Yorkshire and Prebendary of Lincoln Cathedral. Incidentally, he married an heiress and perhaps she, too, did much to make that invention possible. Thanks to the late Lord Masham's father, his memory is perpetuated by the Cartwright Memorial Hall in Lister Park.

My predecessor has handed on to me the difficult task of delivering a presidential address, and my only comfort is that you will not be allowed to express any criticisms upon my efforts. Reflections on the past and prophecies about the future are time-honoured but very hackneyed topics, but I am going to say something to-night about "The Yesterday, the To-day, and the To-morrow" of medicine.

I think that we are tending to lose our veneration for the past: perhaps we are too conceited about our present, and expect too much of the future. It is only human nature when most of us smile superciliously at the lack of scientific knowledge of our early medical ancestors and fail to appreciate the magnificent courage and perseverance with which they fought a losing battle against disease. Rudyard Kipling accurately described our modern mental attitude when he wrote:—

> "Wonderful little, when all is said,
> Wonderful little, our fathers knew,
> Half their remedies cured you dead,
> Most of their teaching was quite untrue."

PUBLIC HEALTH IN CAPE TOWN.

WE have received from Dr. T. Shadick Higgins the annual health report of Cape Town for the year ended June 30th, 1923. Dr. Higgins only took over the duties on June 18th, 1923, so that the period dealt with shows the health position at the beginning of his term of office. It may therefore be of interest to give a table showing some of the principal health statistics for the European and non-European populations respectively, for comparison with English districts.

Race.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Diseases respiratory system.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
European . ..	107,430	22·3	11·1	0·7	0·9	1·4	30	82	4·6
Non-European .	83,590	51·5	29·2	4·2	0·5	8·1	50	200	4·6

It will be noted that the statistics of the European population of Cape Town do not differ appreciably from those of a clean-aired English town, while the non-European population has a very high birth-rate and an excessive death-rate from all causes, tuberculosis and respiratory diseases, the death-rate from cancer being low and the maternity mortality from childbirth being equal to that of the Europeans. Dr. Higgins, in presenting the report, pays a tribute to the good work of his predecessor, Dr. A. Jasper Anderson, the first whole-time medical officer of health for the city, who gave up his appointment on March 31st, 1923, after over 21 years' service.

A study of the report makes it obvious that public health problems in Cape Town are not essentially different from those in the old country. Thus, among the admissions to the City Hospital for Infectious Diseases, the only unusual ailments are one fatal case of anthrax, and one case of Malta fever which recovered. Enteric fever heads the list numerically, as might have happened in an English hospital during the 'eighties of last century. In the table giving the causes of death, the most striking features are the prominence of enteric fever among both races, and of diarrhœa, disease of the stomach, enteritis, syphilis, bronchitis, and pneumonia amongst the non-European population. During the year seven cases of leprosy were notified, one European female and three each of non-European males and females. There were no deaths from leprosy recorded. An outbreak of influenza occurred during June, 1922, and continued into the year under review, and was accountable for seven European and five non-European deaths. As in many parts of England, a small-pox hospital serves the purpose of many surrounding districts. The report of the maternity and child welfare work, submitted by Dr. Mary van Ingen, shows that this department is administered on similar lines to those at home. There are ten sanitary inspectresses and a chief. The notification of every child born after the completion of the sixth month of pregnancy, whether alive or dead, is required within 24 hours. Of 7088 births notified during the year, 6337 were notified by midwives and nurses, 740 by parents and others, and 11 by doctors. Five bureaus for infant consultations are in operation, and their work continues to increase. Voluntary workers give their help. Minor ailments are treated at the bureaus, dried mild is supplied to infants who cannot be breast-fed, and free dinners are provided at two centres for poor nursing mothers. A sanatorium is needed for tuberculosis, as the accommodation in the infectious diseases hospital is inadequate. Last year 100 cases were admitted to the last-named hospital. Dr. W. P. Cooney, in his report as to the work of the male V.D. centre, emphasises the need for education of the public, and points out that suitably trained coloured and native lecturers would do an immense amount of good in this direction.

As examples of the prevalence of venereal disease in Cape Town, he mentions one household where three servants out of five were suffering from syphilis, one being in an infectious state, and a public institution in which four members of the staff were sufferers, two of whom, one infectious, were concerned with food preparation. The want of proper homes, lack of education, and the almost complete absence of moral sense in a number of patients attending the clinic are some of the difficulties. One of the greatest dangers is supplied by the large floating population of the casual type who sleep in the open and cannot be induced to attend for regular treatment. In spite of these difficulties only one case of "accidentally acquired" syphilis was noted during the past year. One definite case of reinfection of syphilis was also noted. In her account of the female V.D. clinic, Dr. Mary van Ingen shows that 64 pregnant women were treated, and that of these 32 gave birth to healthy infants, 20 ceased to attend with results unknown, one infant was born with spina bifida and died at 17 days old, while the remaining five whose treatment was insufficient had stillbirths or infants who developed syphilis. Three of the last-mentioned five only came up for treatment during the last month of pregnancy.

New regulations for protecting the milk-supply were introduced in October, 1922, and follow lines which are familiar in this country. Attention is given to the protection of meat while on sale by the provision of fly- and dust-proof screens, and improvements have been made in the type of carts and wagons used in the conveyance of meat. During the summer months two men are constantly employed in dealing with the mosquito and fly nuisance. Two deaths of Europeans from malaria were recorded during the year—one at the age-period 1 to 5, and the other at the age-period 35 to 45.

A large amount of work has been done in repairing and improving insanitary property, but owing to the scarcity of houses the council has been holding its hand with regard to closing of houses.

JUNKET POWDER.

Messrs. Edward Birks and Son, 88, Castle-street, Reading, have submitted to us a sample of junket powder which consists of active rennet in a desiccated form. Our tests have shown that junket made by its use possesses all the qualities of that made with liquid rennet, while the dry powder keeps its qualities unimpaired and has the additional advantage of being easily portable. Birks's junket powder is sold in bottles from 4½*d.* to 3*s.* 6*d.*, and a small wooden measure is supplied with each bottle.

ARE WHITE CATS WITH BLUE EYES DEAF?

To the Editor of THE LANCET.

SIR,—There is an interesting article in the *Quarterly Journal of Medicine*, April, 1924, by Dr. Stobie, on the association of blue sclerotics with brittle bones and progressive deafness. I was not aware of the associated deafness till I read this recently. Long ago I read the statement—I rather think in one of Darwin's works—that white cats with blue eyes are always deaf. I have once or twice been able to verify this, though not recently, but I would suggest that the coincidence is sufficiently striking to make it worth while to follow up this interesting problem in comparative pathology to see whether the resemblance is more than superficial. I feel fairly sure that in one case the same features appeared in some of the kittens, but I did not look closely at the sclera or do more than satisfy myself as to the deafness.

I am, Sir, yours faithfully,
EDMUND HOBHOUSE.

Brechin-place, S.W., July 10th, 1924.

CLERGYMEN AND HOUSEMAID'S KNEE.

IN the recent Conjoint Examination a candidate, who had already given evidence of common sense as well as surgical acumen, was asked by one of the examining surgeons why clergymen did not suffer from housemaid's knee. The answer desired was that housemaids habitually strain to scrub or dust more ground when kneeling on one spot than they can conveniently reach, and therefore poise themselves on the patella with their heels in the air; whereas clergymen kneel decorously on the tuberosity of the tibia, almost sitting on their heels. This is an ingenious suggestion which might well form a subject of instruction for domestic workers.

Portable Radiographs.—The telephonic address of this firm at 1, Woodstock-road, Bedford Park, London, W. 4, on whose work we commented in last week's issue of THE LANCET, is *Chiswick 2162.*

An Address

ON

YESTERDAY, TO-DAY, AND TO-MORROW.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association in Bradford on July 22nd, 1924,

BY J. BASIL HALL, M.A., M.CH. CAMB.,
HONORARY CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY.

MY LORD BISHOP, LADIES AND GENTLEMEN,—As a Bradford citizen, my first words must be those of a very warm welcome to the British Medical Association. As the President of that Association, on the other hand, I can truly say that I, and every other member of it, have greatly appreciated the very cordial and hospitable reception which the citizens of Bradford have given to us. Although our Association has existed for upwards of 90 years without visiting this city, I can assure you that it was recognised long ago that Bradford had only to be asked and a generous response would be forthcoming.

There is an incident in the history of this city which coincides with the birth of the British Medical Association. In 1832 the Association came into being, and almost simultaneously the town of Bradford was granted the privilege of returning two Members of Parliament. Whether this privilege proved a boon to the city or otherwise I do not know, because I am ignorant of the political views which those Members held. I can only say that I hope they coincided with my own. As regards the birth of the British Medical Association, however, I have no doubts. That great body has done an unspeakable service in binding together the great mass of the medical profession into one solid professional unity. At its inauguration in Worcester by Sir Charles Hastings some 50 original members were enrolled. To-day its membership numbers 27,000 members, scattered over the whole world, and it can justly claim that its voice is the voice of a profession throughout an empire upon which the sun never sets.

I am not going to weary you by recording all that this great Association has accomplished during its long existence, but I cannot refrain from mentioning what I regard as its greatest achievement. When war broke out in 1914 our army was served by the Royal Army Medical Corps. That is a very small body, large enough to give medical service to our soldiers in times of peace, but totally inadequate to meet the requirements of a great war. The British Medical Association promptly established a central war committee and through it provided for our army a regular and organised supply of medical officers throughout the whole campaign. The cost of that patriotic service amounted to £20,000, and it is the proud boast of this country to-day that the care of the sick and wounded has never been equalled in the previous history of the world. If the Association had never done anything else, its war record has more than justified its existence.

Before proceeding further I want to express my very sincere thanks for the loyal and unstinted help which has been so generously given in order that this meeting, the first of its kind in Bradford, should prove a success. When I look back upon the past 12 months and try to realise all the generous service which has been so willingly rendered, I feel that I cannot adequately express my thanks. To name some and omit others would appear invidious, but I must mention our Lord Mayor and others who represent the corporation of this city; and I would especially thank the ladies' committees who have done such yeomen service. Even in the Garden of Eden Adam was a failure till Eve came along, and although she let him down very badly to begin with, she has since earned his eternal gratitude, and we recognise to-day that without her coöperation our annual meetings must prove a failure.

A gathering like this is not merely a national conference. It is something which knits together a professional brotherhood which extends throughout the world. It brings together representatives from all parts of the British Isles, from our overseas dominions, and from the great contingents of Europe and America. It accepts representatives of all those who work with a common object from nations outside our Empire, and it welcomes them as members of a great medical fraternity. There is no such word as "foreign" in the world of medicine. Politicians talk about a League of Nations, but in medicine nations count as nothing. The fight against disease is carried on wherever the human race exists, and we recognise that each does his best according to the knowledge vouchsafed to him. I was told recently that Bradford had no medical traditions and its reputation had still to be made. I accepted the insult with equanimity because I felt I was in the company of several to whom I could bow the knee without humiliation. My mind went back to Dr. Sharpe and to the first Dr. Meade, both Fellows of the Royal Society; and then to the late Dr. John Bell, Dr. Goyder, and others who demonstrated that woolsorters' disease was due to the anthrax bacillus. Also to the late Sir Thomas Stephenson, who became adviser to the Home Office in medical jurisprudence, and who, by his expert evidence, brought many criminals to justice. Then to the most kind-hearted little man I ever knew, the late Dr. Major, an expert in mental disease, one whose whole desire in life was to help everybody. In later days there remains with us the memory of Dr. James Kerr, who left Bradford to become the medical officer of the London School Board—a brilliant scholar, who never realised how brilliant he was even when it was impressed upon him by others. Perhaps I ought not to say anything about those who still remain with us, but I am tempted to express my admiration for the long and patient work which has been given to the effort to discover a sure means of disinfection of wool without destroying its commercial value, and I hope that this will one day obtain success and a well-deserved recognition.

Bradford is essentially a commercial centre, and its citizens respect everyone who advances commercial prosperity. They are enthusiastic in promoting education which has a practical and not merely an academic value. Nevertheless, it is a curious fact, if history be true, that the city owes much of its prosperity to a clergyman. The invention of the power loom emanated from Dr. Cartwright, a Fellow of Magdalen College, Oxford, afterwards incumbent of Brampton in Yorkshire and Prebendary of Lincoln Cathedral. Incidentally, he married an heiress and perhaps she, too, did much to make that invention possible. Thanks to the late Lord Masham's father, his memory is perpetuated by the Cartwright Memorial Hall in Lister Park.

My predecessor has handed on to me the difficult task of delivering a presidential address, and my only comfort is that you will not be allowed to express any criticisms upon my efforts. Reflections on the past and prophecies about the future are time-honoured but very hackneyed topics, but I am going to say something to-night about "The Yesterday, the To-day, and the To-morrow" of medicine.

I think that we are tending to lose our veneration for the past: perhaps we are too conceited about our present, and expect too *much* of the future. It is only human nature when most of us smile superciliously at the lack of scientific knowledge of our early medical ancestors and fail to appreciate the magnificent courage and perseverance with which they fought a losing battle against disease. Rudyard Kipling accurately described our modern mental attitude when he wrote:—

> "Wonderful little, when all is said,
> Wonderful little, our fathers knew,
> Half their remedies cured you dead,
> Most of their teaching was quite untrue."

But having written it, he pays them just tribute by adding :—

> " Yet when sickness was sore in the land,
> When neither planet nor herb assuaged,
> They took their lives in their lancet hand,
> And, oh, what a wonderful war they waged !
> Yes, when the crosses were chalked on the door,
> Yes, when the terrible death cart rolled,
> Excellent courage our fathers bore,
> Excellent hearts had our fathers of old,
> None too learned, yet nobly bold,
> Into the fight went our fathers of old."

The whole world of medicine has so completely changed that we can obtain no true perspective of those early times. The medical student of to-day cannot visualise the conditions against which his predecessors fought. In our eagerness to obtain scientific knowledge and our confidence in modern methods we are losing sight of the traditions of the past. Some of them may be quite untrue in the light of modern knowledge, but many of them still remain as a sure and solid foundation of good practice. Moreover, whatever we may think of the lack of knowledge in the early periods of medicine, there has been handed down to us a precept which every one of us might well adopt as a guiding principle in professional life. Two hundred years ago there lived a great French surgeon, Guy de Chauillac. His epitaph remains to-day as a motto for us all. He lived in a decadent period. He fought and successfully overcame many foolish and superstitious doctrines which were then in vogue. His life was a stormy one, a fight against prejudice and superstition, and when it ended, his service was recognised by an epitaph which he had truly earned :—

> " Bold when sure,
> Cautious in danger,
> Kind to the sick,
> Friendly with fellow-workers,
> Not greedy of gain."

Knowledge is a priceless possession, but the mere acquirement of it derived from the labour of others goes a very short way towards the formation of a career which will give a lasting benefit to mankind. Moreover, it has an ever-varying and ever-changing value. What we take pride in to-day will be regarded as crude and foolish to-morrow, but that indefinable quality, character, and wisdom in the application of knowledge will make our memory live.

During the Victorian era two great discoveries were made which paved the way for the surgical triumphs of to-day. Strictly speaking, neither of them were discoveries, but rather the wise application of scientific knowledge to a practical use. The properties of nitrous oxide gas had been known long before it was suggested that its use might enable surgical operations to be performed during a period of unconsciousness. Pasteur's researches suggested to Lister that their practical application in surgery had great possibilities, and by his wise application of those researches he handed down to us an unspeakable blessing to humanity. It has been truly said that Lister by his teachings has saved more lives than Napoleon destroyed ; and the introduction of the use of anæsthesia has given us the greatest of God's gifts—the relief from pain. Anæsthesia in surgical operations abolished the dread of pain ; and Lister's application of the germ theory destroyed the spectre of septic infection. Every civilised nation pays homage to Lord Lister to-day, and no less to Pasteur. Their names are known and revered throughout the whole world.

It is a curious fact, however, that the circumstances of the birth of anæsthesia have been almost forgotten. Horace Wells, a dentist in Hartford, Connecticut, first conceived and put into practice the principle of inducing unconsciousness during dental operations by the inhalation of nitrous oxide gas. In December, 1844, he induced a friend to administer the gas to him for the extraction of a tooth, and encouraged by success he repeated the experiment on others. He subsequently gave a demonstration in Boston of his methods ; but whether from nervousness, or from some other cause, the demonstration proved unsatisfactory and he was pronounced an impostor. Disheartened at length by the failure of repeated attempts to establish his claims, his mind became unhinged, and for a time he wandered about the streets in New York. On Jan. 4th, 1848, he was arrested on a charge of vitriol throwing, and while he was in gaol he committed suicide. Thus closed, at the age of 32 years, the career of Horace Wells, to whom at least belongs the credit of having first shown the practicability of producing unconsciousness by nitrous oxide gas, and of having thus, in his own words, established " the principle of anæsthesia."

The use of ether as an anæsthetic was introduced in 1846 by Morton, Horace Wells's partner. It was suggested to him by Charles Jackson, a chemist in Boston. Disputes as to priority arose, and Morton died, bankrupt and broken-hearted, after repeated efforts to secure recognition. Jackson, like Wells, became insane, and died in an asylum. Such is the tragic history of the birth of one of the two greatest benefits which have ever been bestowed on suffering humanity. It is recorded that the great American surgeon, Bigelow, after witnessing one of the early experiments in operating under anæsthesia, rushed out into the street exclaiming, " I have seen something to-day that will go round the whole world ! " His prophecy has proved correct ; but I doubt whether he realised the full extent of the meaning of his words. A short time ago it was proposed that a public memorial should be raised to Horace Wells in New York, but the municipal authorities declined to entertain the suggestion. This year the Lister Memorial block of the infirmary in Glasgow is being pulled down to make room for extensions and alterations. Am I not justified in saying that we are losing our veneration for the traditions of the past ? It may be argued that Glasgow is only a very small corner of the world, and Lister's memory will always be revered throughout the whole universe. Nevertheless, while we boast to-day about all the wonderful feats we can and do perform, how many of us give a thought to the poor little dentist who first conceived the possibility of bringing them within our range.

The recent war introduced a period in the history of medicine during which everything was subordinated to the requirements of military service. It was a service which presented special problems and conditions of which we had no previous conception. No one had fully realised the enormous power of high explosives and the destructive capacity of all the devices of modern warfare. During the first few weeks of the war our confidence in the principles of our routine surgical practice were rudely shaken, and it was speedily recognised that special methods of wound treatment must be devised to meet the extraordinary conditions with which we had to deal. Those special methods were not long delayed. At the outset tetanus and gas gangrene threatened to produce an appalling mortality amongst the wounded. In a very short space of time, thanks to the adoption of preventive inoculation, deaths from tetanus became a negligible quantity. At the same time a special surgical technique, almost grotesque in its extravagance, was devised to prevent the occurrence of gas gangrene, and this most terrible and fatal form of wound infection soon became little more than a nightmare of the past. I had the privilege of serving in the Mediterranean force during the second and third years of the war. I never saw a single case of tetanus, and I can only remember one fatal case of gas gangrene. Our victory over these scourges of every army in past history was gained by methods which were inspired by the teaching of two men, Pasteur and Lister. If there is nothing else which should bind England and France together in a bond of everlasting friendship, surely the memory of these two men is sufficient to make us realise that humanity owes a great debt to both nations, a debt which the world can surely never forget.

I do not think, however, that our recent military experiences have done much to advance our usefulness in dealing with sickness in civil life. The demands of war service, the urgent necessity for getting men back into the firing line, or of discharging them from hospital in order to make room for others, created a perfect orgy of exaggerated methods of treatment. Mr. Hamilton Russell, of Melbourne, truly wrote a few years ago: "The present methods of wound treatment have arisen largely by reason of the special character of war injuries as distinguished from those seen in civil practice. The injuries of civil life, however, remain what they were before, and it is necessary to exercise a wise discretion in introducing methods appropriate to war injuries into the much milder type of cases usual in civil life."

The whole war period brought into focus an exaggerated idea of the importance of surgical technique, and cramped the development of surgical judgment. The treatment of every injury and every disease became standardised, and each was passed through the same mill without consideration of qualifying circumstances. It was a bad training for the newly-qualified student of medicine. He was forced to deal with cases and not with patients, and my own personal experience convinced me that the loyal service which our young men so gladly gave to the nation impaired their subsequent usefulness in civil life. Each became a mere cogwheel in a great machine designed to fulfil a special purpose. During the most impressionable period of their career they worked amongst all the sensational excitement associated with military service, and "the daily round and common task" of civil practice is now an irksome experience for them. Hence is largely derived the widespread desire to practise some form of specialism. Specialism has become an idol which all and sundry worship. Not very long ago a well-known teacher in a great London school deplored this modern tendency in medicine. He said: "Everything is becoming divided into special classes and clinics, and the lecturer deals with his students as embryo specialists in the subjects in which he himself is expert. The necessary solid foundation of general knowledge upon which specialism should be built is receiving too scant attention, and the rising generation is being taught to run before it has learnt to walk." The late Sir William Macewen, whose recent death we deplore, once said, "No one can become a good surgeon unless he is first a good physician." It is an axiom which we should never forget, and it behoves every one to equip himself with a wide knowledge of general medicine before attempting to launch his boat upon the stormy sea of operative surgery. To the layman the term specialist has become a cabalistic word which he repeats upon every possible occasion. There is, however, *one* specialism which he frequently fails to appreciate at its proper value—the specialism of general practice. It requires more knowledge of human nature, and more experience over a wide field of observation, to make a really first-class general practitioner than the public has any cognisance of.

It would be absurd to depreciate the value of the many scientific methods of investigation which are available at the present time, but I am sure that a too ready appeal to them is doing much to destroy the initiative in the younger generation to think for themselves. Clinical observation threatens to become a lost art. Radiography and all the modern scientific methods are good servants but bad masters. There is a whole world of wisdom in an anecdote I heard recently. A patient presented himself before a surgeon, armed with a bundle of X ray photographs and reports of various kinds. The surgeon put them all on one side and said; "We will look at these presently, but in the meantime just get on to that couch and I will endeavour to find out what you are suffering from. After that, all these things *may* help to prove whether I am right or wrong."

I would insist, therefore, that our present failing is an over-confidence in modern technique and a lack of appreciation of the value of that wisdom which can only be obtained by personal observation and experience. I would urge the younger generation to think more and observe more for themselves, as their forefathers did, and not be so ready to bow the knee in a fanatical worship of so-called scientific methods of investigation and treatment. I would ask them to reflect on all the special methods which have been put forward during the past 35 years, from tuberculin down to deep X ray therapy for cancer, to realise how many have failed to stand the test of experience, and to reflect on all the bitter disappointments which have been inflicted by the thoughtless optimism with which each has been advocated. Our scientific knowledge has been greatly advanced, but knowledge avails us very little unless we cultivate the wisdom to gauge its practical value and apply it usefully:—

> "Knowledge and wisdom, far from being one
> Have oft times no connexion; knowledge dwells
> In heads replete with thoughts of other men,
> Wisdom in minds attentive to their own.
> Knowledge is proud that he has learned so much,
> Wisdom is humble that he knows no more."

What of the future? The day is coming when it will cease to be said that—

> "We are afflicted by what we can prove,
> We are distracted by what we know,"

because we shall obtain presently a truer perspective of the scientific methods of to-day. Experience, begotten by patient observation, will teach us their real value and their limitations. Some will be discarded, some may become a sheet anchor in times of doubt. Each will add their quota to our knowledge if they be wisely used, and not merely applied empirically just because they appeal to the popular craze of the moment. We must each play our part by developing our personal observation and experience, and not be content to invoke specialisms to solve those problems which we ought to decide for ourselves. If we do that we shall each add something to the sum of human happiness; and that, after all, is the one thing worth living for. Then when we have grown old, and the world has forgotten what we have done in the past, we shall find comfort in that consolation which has been given to every one who has striven to do his best:—

> "When earth's *last* picture is painted, and the tubes are twisted and dried,
> When the oldest colours have faded, and the youngest critic has died,
> We shall rest; and faith we shall need it, lie down for an æon or two
> Till the Master of all good workmen will put us to work anew.
> And only 'The Master' shall *praise us, and only* 'The Master' shall blame,
> And no one shall work for money, and no one shall work for fame,
> But each *for joy of the* working, and each in his separate star,
> Shall paint the things as he sees them for the God of things as they are."

An Address

ENTITLED

IS THE STATISTICAL METHOD OF ANY VALUE IN MEDICAL RESEARCH?

Delivered in the Institute of Pathology and Research, St. Mary's Hospital, on May 22nd, 1924,

BY MAJOR GREENWOOD, F.R.C.P. LOND.,
MEDICAL OFFICER (MEDICAL STATISTICS), MINISTRY OF HEALTH.

I RECOGNISE that there is a touch of disingenuousness in my choice of title; few human passions are stronger than vanity, and there are not many men whose love of truth is so compelling that they can stand up and confess to their fellows that the studies to which they have devoted many years are futile. I am not one of those rare spirits: the fact that I ask this question implies that I think I can answer it affirmatively, so I am an advocate, not a judge. But this I can plead in extenuation; my opinion of the statistical method has changed in the 20 years during which it has been my principal study: in some ways I value it more, in others less, than I did

But having written it, he pays them just tribute by adding:—

" Yet when sickness was sore in the land,
When neither planet nor herb assuaged,
They took their lives in their lancet hand,
And, oh, what a wonderful war they waged!
Yes, when the crosses were chalked on the door,
Yes, when the terrible death cart rolled,
Excellent courage our fathers bore,
Excellent hearts had our fathers of old,
None too learned, yet nobly bold,
Into the fight went our fathers of old."

The whole world of medicine has so completely changed that we can obtain no true perspective of those early times. The medical student of to-day cannot visualise the conditions against which his predecessors fought. In our eagerness to obtain scientific knowledge and our confidence in modern methods we are losing sight of the traditions of the past. Some of them may be quite untrue in the light of modern knowledge, but many of them still remain as a sure and solid foundation of good practice. Moreover, whatever we may think of the lack of knowledge in the early periods of medicine, there has been handed down to us a precept which every one of us might well adopt as a guiding principle in professional life. Two hundred years ago there lived a great French surgeon, Guy de Chauillac. His epitaph remains to-day as a motto for us all. He lived in a decadent period. He fought and successfully overcame many foolish and superstitious doctrines which were then in vogue. His life was a stormy one, a fight against prejudice and superstition, and when it ended, his service was recognised by an epitaph which he had truly earned:—

" Bold when sure,
Cautious in danger,
Kind to the sick,
Friendly with fellow-workers,
Not greedy of gain."

Knowledge is a priceless possession, but the mere acquirement of it derived from the labour of others goes a very short way towards the formation of a career which will give a lasting benefit to mankind. Moreover, it has an ever-varying and ever-changing value. What we take pride in to-day will be regarded as crude and foolish to-morrow, but that indefinable quality, character, and wisdom in the application of knowledge will make our memory live.

During the Victorian era two great discoveries were made which paved the way for the surgical triumphs of to-day. Strictly speaking, neither of them were discoveries, but rather the wise application of scientific knowledge to a practical use. The properties of nitrous oxide gas had been known long before it was suggested that its use might enable surgical operations to be performed during a period of unconsciousness. Pasteur's researches suggested to Lister that their practical application in surgery had great possibilities, and by his wise application of those researches he handed down to us an unspeakable blessing to humanity. It has been truly said that Lister by his teachings has saved more lives than Napoleon destroyed; and the introduction of the use of anæsthesia has given us the greatest of God's gifts—the relief from pain. Anæsthesia in surgical operations abolished the dread of pain; and Lister's application of the germ theory destroyed the spectre of septic infection. Every civilised nation pays homage to Lord Lister to-day, and no less to Pasteur. Their names are known and revered throughout the whole world.

It is a curious fact, however, that the circumstances of the birth of anæsthesia have been almost forgotten. Horace Wells, a dentist in Hartford, Connecticut, first conceived and put into practice the principle of inducing unconsciousness during dental operations by the inhalation of nitrous oxide gas. In December, 1844, he induced a friend to administer the gas to him for the extraction of a tooth, and encouraged by success he repeated the experiment on others. He subsequently gave a demonstration in Boston of his methods; but whether from nervousness, or from some other cause, the demonstration proved unsatisfactory and he was pronounced an impostor. Disheartened at length by the failure of repeated attempts to establish his claims, his mind became unhinged, and for a time he wandered about the streets in New York. On Jan. 4th, 1848, he was arrested on a charge of vitriol throwing, and while he was in gaol he committed suicide. Thus closed, at the age of 32 years, the career of Horace Wells, to whom at least belongs the credit of having first shown the practicability of producing unconsciousness by nitrous oxide gas, and of having thus, in his own words, established " the principle of anæsthesia."

The use of ether as an anæsthetic was introduced in 1846 by Morton, Horace Wells's partner. It was suggested to him by Charles Jackson, a chemist in Boston. Disputes as to priority arose, and Morton died, bankrupt and broken-hearted, after repeated efforts to secure recognition. Jackson, like Wells, became insane, and died in an asylum. Such is the tragic history of the birth of one of the two greatest benefits which have ever been bestowed on suffering humanity. It is recorded that the great American surgeon, Bigelow, after witnessing one of the early experiments in operating under anæsthesia, rushed out into the street exclaiming, " I have seen something to-day that will go round the whole world!" His prophecy has proved correct; but I doubt whether he realised the full extent of the meaning of his words. A short time ago it was proposed that a public memorial should be raised to Horace Wells in New York, but the municipal authorities declined to entertain the suggestion. This year the Lister Memorial block of the infirmary in Glasgow is being pulled down to make room for extensions and alterations. Am I not justified in saying that we are losing our veneration for the traditions of the past? It may be argued that Glasgow is only a very small corner of the world, and Lister's memory will always be revered throughout the whole universe. Nevertheless, while we boast to-day about all the wonderful feats we can and do perform, how many of us give a thought to the poor little dentist who first conceived the possibility of bringing them within our range.

The recent war introduced a period in the history of medicine during which everything was subordinated to the requirements of military service. It was a service which presented special problems and conditions of which we had no previous conception. No one had fully realised the enormous power of high explosives and the destructive capacity of all the devices of modern warfare. During the first few weeks of the war our confidence in the principles of our routine surgical practice were rudely shaken, and it was speedily recognised that special methods of wound treatment must be devised to meet the extraordinary conditions with which we had to deal. Those special methods were not long delayed. At the outset tetanus and gas gangrene threatened to produce an appalling mortality amongst the wounded. In a very short space of time, thanks to the adoption of preventive inoculation, deaths from tetanus became a negligible quantity. At the same time a special surgical technique, almost grotesque in its extravagance, was devised to prevent the occurrence of gas gangrene, and this most terrible and fatal form of wound infection soon became little more than a nightmare of the past. I had the privilege of serving in the Mediterranean force during the second and third years of the war. I never saw a single case of tetanus, and I can only remember one fatal case of gas gangrene. Our victory over these scourges of every army in past history was gained by methods which were inspired by the teaching of two men, Pasteur and Lister. If there is nothing else which should bind England and France together in a bond of everlasting friendship, surely the memory of these two men is sufficient to make us realise that humanity owes a great debt to both nations, a debt which the world can surely never forget.

I do not think, however, that our recent military experiences have done much to advance our usefulness will prevent us from discerning the general laws of the collectivity. Perhaps the old London tradesman might have used of his method the words of a physician whom Sydenham loved: "Ὅστις δὲ ταῦτα ἀποβαλὼν καὶ ἀποδοκιμάσας πάντα ἑτέρῃ ὁδῷ καὶ ἑτέρῳ σχήματι ἐπιχειρέει ζητέειν, καὶ φήσει τι εὑρηκέναι, ἐξηπάτηται καὶ ἐξαπατᾶται· ἀδύνατον γάρ. (He who, casting aside and rejecting all these methods, essays to find truth by another path and with another method and proclaims that he has discovered something is deceiving and deceived. The thing is impossible.)

IS THE STATISTICAL METHOD EXHAUSTED?

But my candid critic may accept all this and still refuse to recognise the modern statistician as a scientific investigator. He will say: "I am quite prepared to recognise that Graunt and those inspired by him did valuable work. I agree that it *was* necessary both for honest propaganda—for calling attention to the existence of great evils which might be remedied—and even for suggesting fruitful topics of *real* research, that systematic vital statistics should be compiled and published. But in the preparation and interpretation of these statistics, one needs no more than plain good sense. Because the results of their labours are useful, the compilers and analysers of these statistics are no more entitled to rank as scientific investigators than are the equally useful artisans who manufacture our laboratory apparatus. Indeed, when I glance at the pages of acrimonious dispute between rival statisticians touching the scientific claims of different 'coefficients' I am reminded of Sam Johnson's remark: 'Sir, there is no settling the point of precedency between a louse and a flea.'"

Let us consider these two perfectly reasonable contentions: (1) That there is, properly speaking, no special method or art of medical statistics, plain good sense is all that is required; (2) that there is no longer any scope for originality in statistical research, that now, after all these years of tabulation and publication, statistics are on the plane of repetitive semi-skilled manufacture.

THE TERRIBLE RESULTS OF COMMON SENSE.

Is it a fact that a man of good sense can be trusted to interpret statistical data without either special training or (as in Graunt's case) special ability? In 1801 Dr. William Heberden the Younger published "Observations on the Increase and Decrease of Different Diseases." Heberden was something more than a mere man of good sense; he was a scholar, an experienced physician, and had family interest in medico-statistical investigations. His father, one of the most famous of eighteenth century physicians, financed a continuation of Graunt's work by Corbyn Morris. Heberden, then, went over the ground fairly acquainted with his predecessor's work and reached a conclusion which attracted a good deal of attention; he said, "there is scarcely any fact to be collected from the bills of mortality more worthy the attention of physicians than the gradual decline of dysentery." Heberden took together the three titles, bloody flux, colic, and griping in the guts, he showed that the annual average was more than 1000 in the first decade of the eighteenth century, fell to 770, to 700, to 350, 150, 110, 80, 70, 40, and finally 20 in the decade 1790–1800. He attributed this decline to greater cleanliness and better ventilation. But, as Creighton pointed out,[3] Heberden had simply made a statistical mistake; he had supposed "griping in the guts" to be dysentery when it really meant infantile diarrhœa; he made this mistake by overlooking the age-incidence of the deaths assigned to griping in the guts and did not notice that the total had been gradually transferred to the rubric convulsions. He *did* notice that the numbers assigned to convulsions had increased, but explained it by the transfer to this heading of chrisomes and infants, but did not remark (*a*) that transfer had been made already while convulsions were still a small total, (*b*) the gross total of chrisomes and infants was never large enough to make a difference of the required order of magnitude. If you compare Heberden's treatment of this case with Graunt's treatment of the question of whether rickets were a "new disease" in or about 1634, I think you will have no difficulty in deciding that Graunt did have a critical faculty which is really something more than simple good sense, and that a very sensible man like Heberden may blunder badly.

It would be easy enough to mention examples more recent than that of Heberden. Such mistakes look very foolish *when they are pointed out;* but a dozen of them will be made by very intelligent men within a year. I think we may accept the proposition that there is a kind of statistical tact, which is rather more than simple good sense; some are born with it, like Graunt; the rest of us have to acquire it. The second point raised by my objector is worth more consideration.

I wish to consider it under two subdivisions—first, when we confine the scope of the statistical method to what Graunt modestly called his shop arithmetic or to developments of that shop arithmetic which would have been quite intelligible to him; secondly, when we bring into the account a modern calculus which would have been almost as hard for Graunt to understand as it is for many, even laboratory workers, in the twentieth century.

LIFE-TABLES.

I choose as an example under the first heading the case of life-tables. Graunt made the first life-table, and the difference between the last English life-table, with its serried ranks of numerals, and the few figures of Graunt is of detail, very important detail of course, not of principle. A life-table purports to tell us how many of a fictitious population born at the same instant will live, 0, 1, 2, &c., years and has been used for two main purposes. The first, to provide a basis for commercial transactions, to make it possible to buy and sell equitably life annuities, assurances upon lives, and other similar conditional payments; the second to effect a summary and graphic comparison between the states of mortality in different communities or different occupations. In *medical research*, in the sense in which most of this audience understand that term, it has been used by very few. In England, my friend, Dr. John Brownlee,[4] is perhaps the only medical man who has devoted close attention to its possibilities as an instrument of research. I am aware that Bardolph was not thought a good security for Falstaff, so I shall not dwell, as I should like to do, upon the researches of a fellow medical statistician but call a witness from the respectable and unstatistical pages of the *Zeitschrift für Allgemeine Physiologie*. In 1921, August Pütter,[5] of Bonn, published an essay in which he argued that the immense literature dealing with the physiology and pathology of the duration of life, a literature to which such men as Weismann and Rubner have contributed, suffers from the lack of any clear idea as to what really is being investigated. He observes that we know more about the course of life in man than in any other animal, and suggests that it would be just as well to start by learning what there is to be learned from life-tables.

Pütter brings to the subject a fresh mind, and, like an intelligent man, sets his imagination to work to discover a *law* of mortality—i.e., some mental shorthand which will describe the increase of mortality with age. He is interested in the physiological problem of senescence, and so he only considers increasing mortality—i.e., from adult age onwards. As a laboratory worker would naturally do, he first takes the analogy of the destruction of bacteria by a disinfectant and considers the law of decrement which describes that case, the logarithmic law, the expression of the waning of a population opposing a constant power of resistance to a constant force of destruction. He suggests the combination with this of a law of geometrically increasing destructive power, so the law of human mortality he finally reaches is compounded of two factors, (1) which measures a

as a youth; perhaps as candid an account of my present position as unconscious vanity will allow me to make will help others to assess fairly the value of the statistical method.

The General Case Against Medical Statistics.

It is generally agreed that statistics of a sort are useful to the medical profession; that, for instance, it is desirable to compute and publish death-rates and records of infectious diseases. But many research workers would deny that data of this kind either ever have been made or ever could be made the subject of a scientific investigation apt to reveal new and important truths, in the sense that the data of experiment can be made to disclose the secrets of nature. Let me try to state the grounds of such an opinion as forcibly as I can.

The medical statistics of any country can, at best, only reflect the opinions of its practitioners of medicine; at worst, they may be a mere translation into figures of the hearsay of laymen, possibly of drunken and venal old women—Graunt's view of the sources of vital statistics in the seventeenth century. Medical statistics between the best and the worst—that is to say, as they are compiled in most civilised countries—record not all the candid opinions of certifying practitioners, but some of their opinions. So long as medical practice is individualistic and death certificates are open to the inspection of the friends of the deceased—as they are in England and Wales—there is some motive to refrain from recording any opinion which may either hurt the credit of the practitioner in the eyes of his clients or do violence to common human sentiments. To subject documents of this order of accuracy to elaborate mathematical manipulation is surely trifling. "How and why did this man die?" is the most tremendous of interrogatories. To answer it fairly and fully may require knowledge and insight which no man has ever had, not Hippocrates, not Sydenham. Our medical statistics are the coding of answers given not by Hippocrates and Sydenham, but by men of only ordinary ability and insight, some ignorant, some biassed. "Dix millions d'ignorances," said Taine, "ne font pas un savoir." No calculus will transmute a million inaccurate verbal statements into an exact numerical appraisement. Can we deduce from this codification of half-truths anything at all which we might not have reached by plain good sense and observation without arithmetic? The Registrar-General tells us that 44,789 persons died of "influenza" in 1919, 112,310 in 1918, and only 7283 in 1917. We needed no statistics to convince us that "influenza" was a great pestilence in 1918, a serious cause of illness in 1919, and relatively unimportant in 1917. The Registrar-General does, indeed, tell us many things we did not know. He says that 29,777 persons were reported to have died of "old age" in 1919, and that four of these ancients were between 45 and 50, 14 between 50 and 55, and 59 between 55 and 60. We also learn from him that "old age" was epidemic in 1909; 33,975 people succumbed to it in that year, but it was much less virulent in 1913 when only 29,801 were cut off. Certainly we did not know these facts until the Registrar-General told us of them; indeed, we do not know them now. Putting it bluntly, what is true in his records is not new to any observant man, and what is new is probably not true. That, I think, is a fair statement of the objections many feel but few express, because, nowadays, statisticians, even medical statisticians, are quite respectable people. Now let us see whether the objection can be met, and met upon ground which is as unfavourable as can well be chosen—viz., the ground of the seventeenth century.

Graunt and Sydenham.

Contemporaneously in London in the seventeenth century two men endeavoured to elucidate the natural history of disease. Each used the same figure of speech and supported it with the same authority. The one averred that "The Observations which I happened to make (for I designed them not) upon the Bills of Mortality, have fallen out to be both Political and Natural, some concerning Trade and Government, others concerning the Air, Countries, Seasons, Fruitfulness, Health, Diseases, Longevity, and the proportions between the Sex and Ages of Mankind. All which (because Sir Francis Bacon reckons his Discourses of Life and Death to be Natural History . . .) I am humbly bold to think Natural History also, and consequently that I am obliged to cast in this small Mite into your great Treasury of that kind."[1] The other, desiderated, "primo Historia, sive morborum omnium descriptio quoad fieri potest graphica et naturalis," and said that, done so that "evitetur censura quam clarissimus Verulamius in nonnullos ejusmodi promissores vibravit," it would be a task not easy of fulfilment.[2]

One of the two was a London tradesman, John Graunt, the other, Thomas Sydenham, *medicus in omne ævum nobilis*. One based his natural history upon tables of figures compiled from the reports of "ancient matrons" whose diagnostic powers were, he thought, affected by the "mist of a cup of Ale and the bribe of a two-groat fee." The other's data were his own careful observations through 20 years of practice in the capital.

Given two men so equipped for the discovery of truth, which was the likelier to find truth, to make known natural historical facts apt to stimulate further research and so lead to further discoveries? Surely the answer is, Sydenham. But if we were to select from the host of natural historical facts of mortality, a fact *now* trite enough, but a novelty 200 years ago, one fact which has inspired more sanitary effort and more laboratory investigation than perhaps any other, it would be, I think, the enormous excess of mortality in childhood in large cities. One of our two natural historians of disease revealed that fact. He said: "We shall find that about 36 *per centum* of all quick conceptions died before six years old." . . . "When I consider, that in the Country 70 are born for 58 buried, and that before the year 1600 the like happened in London, I considered, whether a city as it becomes more populous, doth not, for that very cause, become more unhealthful: and inclined to believe, that London now is more unhealthful than heretofore; partly for that it is more populous, but chiefly because I have heard, that 60 years ago few Sea Coals were burnt in London, which are now universally used."

These are the words not of Sydenham but of Graunt, and how "the observations which I happened to make" led, directly and immediately, to the foundation of scientific methods of life assurance and, indirectly, to the establishment of those national registers of life and death, without which the work of Simon, of Chadwick, of Buchanan, of Power, and of Shirley Murphy could never have been done, is an oft-told tale. To "the observations which I happened to make" may be traced the inspiration of bacteriological researches carried out by men who never heard the name of Graunt.

What inspiration have modern investigators derived from Sydenham? I do not ask what our debt to him might have been had we been wise enough to invest some of the intellectual money he gave us, but what we *actually* owe, what great discoveries made since the seventeenth century are to be directly traced to Sydenham's inspiration. I think the answer is—none whatever. No great intellect is wasted; Sydenham has, perhaps, a debtor still unborn who will make something of "Epidemic Constitutions."

> "That low man seeks a little thing to do,
> Sees it and does it;
> This high man, with a great thing to pursue,
> Dies ere he knows it."

Sydenham was the high man, if you please, and Graunt the low man, but what he sought to do he did do. It is fine to have a soul above mere shop arithmetic, but perhaps unless one does cloak the humanity of one's patients in the guise of mere ciphers and averages, flesh and blood will be too much for us and our interest in the individual happenings

will prevent us from discerning the general laws of the collectivity. Perhaps the old London tradesman might have used of his method the words of a physician whom Sydenham loved: "Ὅστις δὲ ταῦτα ἀποβαλὼν καὶ ἀποδοκιμάσας πάντα ἑτέρῃ ὁδῷ καὶ ἑτέρῳ σχήματι ἐπιχειρέει ζητέειν, καὶ φήσει τι εἰρηκέναι, ἐξηπάτηται καὶ ἐξαπατᾶται· ἀδύνατον γάρ. (He who, casting aside and rejecting all these methods, essays to find truth by another path and with another method and proclaims that he has discovered something is deceiving and deceived. The thing is impossible.)

IS THE STATISTICAL METHOD EXHAUSTED?

But my candid critic may accept all this and still refuse to recognise the modern statistician as a scientific investigator. He will say: "I am quite prepared to recognise that Graunt and those inspired by him did valuable work. I agree that it *was* necessary both for honest propaganda—for calling attention to the existence of great evils which might be remedied—and even for suggesting fruitful topics of *real* research, that systematic vital statistics should be compiled and published. But in the preparation and interpretation of these statistics, one needs no more than plain good sense. Because the results of their labours are useful, the compilers and analysers of these statistics are no more entitled to rank as scientific investigators than are the equally useful artisans who manufacture our laboratory apparatus. Indeed, when I glance at the pages of acrimonious dispute between rival statisticians touching the scientific claims of different 'coefficients' I am reminded of Sam Johnson's remark: 'Sir, there is no settling the point of precedency between a louse and a flea.'"

Let us consider these two perfectly reasonable contentions: (1) That there is, properly speaking, no special method or art of medical statistics, plain good sense is all that is required; (2) that there is no longer any scope for originality in statistical research, that now, after all these years of tabulation and publication, statistics are on the plane of repetitive semi-skilled manufacture.

THE TERRIBLE RESULTS OF COMMON SENSE.

Is it a fact that a man of good sense can be trusted to interpret statistical data without either special training or (as in Graunt's case) special ability? In 1801 Dr. William Heberden the Younger published "Observations on the Increase and Decrease of Different Diseases." Heberden was something more than a mere man of good sense; he was a scholar, an experienced physician, and had family interest in medico-statistical investigations. His father, one of the most famous of eighteenth century physicians, financed a continuation of Graunt's work by Corbyn Morris. Heberden, then, went over the ground fairly acquainted with his predecessor's work and reached a conclusion which attracted a good deal of attention; he said, "there is scarcely any fact to be collected from the bills of mortality more worthy the attention of physicians than the gradual decline of dysentery." Heberden took together the three titles, bloody flux, colic, and griping in the guts, he showed that the annual average was more than 1000 in the first decade of the eighteenth century, fell to 770, to 700, to 350, 150, 110, 80, 70, 40, and finally 20 in the decade 1790–1800. He attributed this decline to greater cleanliness and better ventilation. But, as Creighton pointed out,[2] Heberden had simply made a statistical mistake; he had supposed "griping in the guts" to be dysentery when it really meant infantile diarrhœa; he made this mistake by overlooking the age-incidence of the deaths assigned to griping in the guts and did not notice that the total had been gradually transferred to the rubric convulsions. He *did* notice that the numbers assigned to convulsions had increased, but explained it by the transfer to this heading of chrisomes and infants, but did *not* remark (*a*) that transfer had been made already while convulsions were still a small total, (*b*) the gross total of chrisomes and infants was never large enough to make a difference of the required order of magnitude. If you compare Heberden's treatment of this case with Graunt's treatment of the question of whether rickets were a "new disease" in or about 1634, I think you will have no difficulty in deciding that Graunt did have a critical faculty which is really something more than simple good sense, and that a very sensible man like Heberden may blunder badly.

It would be easy enough to mention examples more recent than that of Heberden. Such mistakes look very foolish *when they are pointed out;* but a dozen of them will be made by very intelligent men within a year. I think we may accept the proposition that there is a kind of statistical tact, which is rather more than simple good sense; some are born with it, like Graunt; the rest of us have to acquire it. The second point raised by my objector is worth more consideration.

I wish to consider it under two subdivisions—first, when we confine the scope of the statistical method to what Graunt modestly called his shop arithmetic or to developments of that shop arithmetic which would have been quite intelligible to him; secondly, when we bring into the account a modern calculus which would have been almost as hard for Graunt to understand as it is for many, even laboratory workers, in the twentieth century.

LIFE-TABLES.

I choose as an example under the first heading the case of life-tables. Graunt made the first life-table, and the difference between the last English life-table, with its serried ranks of numerals, and the few figures of Graunt is of detail, very important detail of course, not of principle. A life-table purports to tell us how many of a fictitious population born at the same instant will live, 0, 1, 2, &c., years and has been used for two main purposes. The first, to provide a basis for commercial transactions, to make it possible to buy and sell equitably life annuities, assurances upon lives, and other similar conditional payments; the second to effect a summary and graphic comparison between the states of mortality in different communities or different occupations. In *medical research*, in the sense in which most of this audience understand that term, it has been used by very few. In England, my friend, Dr. John Brownlee,[4] is perhaps the only medical man who has devoted close attention to its possibilities as an instrument of research. I am aware that Bardolph was not thought a good security for Falstaff, so I shall not dwell, as I should like to do, upon the researches of a fellow medical statistician but call a witness from the respectable and unstatistical pages of the *Zeitschrift für Allgemeine Physiologie.* In 1921, August Pütter,[5] of Bonn, published an essay in which he argued that the immense literature dealing with the physiology and pathology of the duration of life, a literature to which such men as Weismann and Rubner have contributed, suffers from the lack of any clear idea as to what really is being investigated. He observes that we know more about the course of life in man than in any other animal, and suggests that it would be just as well to start by learning what there is to be learned from life-tables.

Pütter brings to the subject a fresh mind, and, like an intelligent man, sets his imagination to work to discover a *law* of mortality—i.e., some mental shorthand which will describe the increase of mortality with age. He is interested in the physiological problem of senescence, and so he only considers increasing mortality—i.e., from adult age onwards. As a laboratory worker would naturally do, he first takes the analogy of the destruction of bacteria by a disinfectant and considers the law of decrement which describes that case, the logarithmic law, the expression of the waning of a population opposing a constant power of resistance to a constant force of destruction. He suggests the combination with this of a law of geometrically increasing destructive power, so the law of human mortality he finally reaches is compounded of two factors, (1) which measures a

as a youth; perhaps as candid an account of my present position as unconscious vanity will allow me to make will help others to assess fairly the value of the statistical method.

THE GENERAL CASE AGAINST MEDICAL STATISTICS.

It is generally agreed that statistics of a sort are useful to the medical profession; that, for instance, it is desirable to compute and publish death-rates and records of infectious diseases. But many research workers would deny that data of this kind either ever have been made or ever could be made the subject of a scientific investigation apt to reveal new and important truths, in the sense that the data of experiment can be made to disclose the secrets of nature. Let me try to state the grounds of such an opinion as forcibly as I can.

The medical statistics of any country can, at best, only reflect the opinions of its practitioners of medicine; at worst, they may be a mere translation into figures of the hearsay of laymen, possibly of drunken and venal old women—Graunt's view of the sources of vital statistics in the seventeenth century. Medical statistics between the best and the worst—that is to say, as they are compiled in most civilised countries—record not all the candid opinions of certifying practitioners, but some of their opinions. So long as medical practice is individualistic and death certificates are open to the inspection of the friends of the deceased—as they are in England and Wales—there is some motive to refrain from recording any opinion which may either hurt the credit of the practitioner in the eyes of his clients or do violence to common human sentiments. To subject documents of this order of accuracy to elaborate mathematical manipulation is surely trifling. "How and why did this man die?" is the most tremendous of interrogatories. To answer it fairly and fully may require knowledge and insight which no man has ever had, not Hippocrates, not Sydenham. Our medical statistics are the coding of answers given not by Hippocrates and Sydenham, but by men of only ordinary ability and insight, some ignorant, some biassed. "Dix millions d'ignorances," said Taine, "ne font pas un savoir." No calculus will transmute a million inaccurate verbal statements into an exact numerical appraisement. Can we deduce from this codification of half-truths anything at all which we might not have reached by plain good sense and observation without arithmetic? The Registrar-General tells us that 44,789 persons died of "influenza" in 1919, 112,310 in 1918, and only 7283 in 1917. We needed no statistics to convince us that "influenza" was a great pestilence in 1918, a serious cause of illness in 1919, and relatively unimportant in 1917. The Registrar-General does, indeed, tell us many things we did not know. He says that 29,777 persons were reported to have died of "old age" in 1919, and that four of these ancients were between 45 and 50, 14 between 50 and 55, and 59 between 55 and 60. We also learn from him that "old age" was epidemic in 1909; 33,975 people succumbed to it in that year, but it was much less virulent in 1913 when only 29,801 were cut off. Certainly we did not know these facts until the Registrar-General told us of them; indeed, we do not know them now. Putting it bluntly, what is true in his records is not new to any observant man, and what is new is probably not true. That, I think, is a fair statement of the objections many feel but few express, because, nowadays, statisticians, even medical statisticians, are quite respectable people. Now let us see whether the objection can be met, and met upon ground which is as unfavourable as can well be chosen—viz., the ground of the seventeenth century.

GRAUNT AND SYDENHAM.

Contemporaneously in London in the seventeenth century two men endeavoured to elucidate the natural history of disease. Each used the same figure of speech and supported it with the same authority. The one averred that "The Observations which I happened to make (for I designed them not) upon the Bills of Mortality, have fallen out to be both Political and Natural, some concerning Trade and Government, others concerning the Air, Countries, Seasons, Fruitfulness, Health, Diseases, Longevity, and the proportions between the Sex and Ages of Mankind. All which (because Sir Francis Bacon reckons his Discourses of Life and Death to be Natural History . . . .) I am humbly bold to think Natural History also, and consequently that I am obliged to cast in this small Mite into your great Treasury of that kind."[1] The other, desiderated, "primo Historia, sive morborum omnium descriptio quoad fieri potest graphica et naturalis," and said that, done so that "evitetur censura quam clarissimus Verulamius in nonnullos ejusmodi promissores vibravit," it would be a task not easy of fulfilment.[2]

One of the two was a London tradesman, John Graunt, the other, Thomas Sydenham, *medicus in omne œvum nobilis*. One based his natural history upon tables of figures compiled from the reports of "ancient matrons" whose diagnostic powers were, he thought, affected by the "mist of a cup of Ale and the bribe of a two-groat fee." The other's data were his own careful observations through 20 years of practice in the capital.

Given two men so equipped for the discovery of truth, which was the likelier to find truth, to make known natural historical facts apt to stimulate further research and so lead to further discoveries? Surely the answer is, Sydenham. But if we were to select from the host of natural historical facts of mortality, a fact *now* trite enough, but a novelty 200 years ago, one fact which has inspired more sanitary effort and more laboratory investigation than perhaps any other, it would be, I think, the enormous excess of mortality in childhood in large cities. One of our two natural historians of disease revealed that fact. He said: "We shall find that about 36 *per centum* of all quick conceptions died before six years old." . . . "When I consider, that in the Country 70 are born for 58 buried, and that before the year 1600 the like happened in London, I considered, whether a city as it becomes more populous, doth not, for that very cause, become more unhealthful: and inclined to believe, that London now is more unhealthful than heretofore; partly for that it is more populous, but chiefly because I have heard, that 60 years ago few Sea Coals were burnt in London, which are now universally used."

These are the words not of Sydenham but of Graunt, and how "the observations which I happened to make" led, directly and immediately, to the foundation of scientific methods of life assurance and, indirectly, to the establishment of those national registers of life and death, without which the work of Simon, of Chadwick, of Buchanan, of Power, and of Shirley Murphy could never have been done, is an oft-told tale. To "the observations which I happened to make" may be traced the inspiration of bacteriological researches carried out by men who never heard the name of Graunt.

What inspiration have modern investigators derived from Sydenham? I do not ask what our debt to him might have been had we been wise enough to invest some of the intellectual money he gave us, but what we *actually* owe, what great discoveries made since the seventeenth century are to be directly traced to Sydenham's inspiration. I think the answer is—none whatever. No great intellect is wasted; Sydenham has, perhaps, a debtor still unborn who will make something of "Epidemic Constitutions."

> "That low man seeks a little thing to do,
> Sees it and does it;
> This high man, with a great thing to pursue,
> Dies ere he knows it."

Sydenham was the high man, if you please, and Graunt the low man, but what he sought to do he did do. It is fine to have a soul above mere shop arithmetic, but perhaps unless one does cloak the humanity of one's patients in the guise of mere ciphers and averages, flesh and blood will be too much for us and our interest in the individual happenings

will prevent us from discerning the general laws of the collectivity. Perhaps the old London tradesman might have used of his method the words of a physician whom Sydenham loved: "Ὅστις δὲ ταῦτα ἀποβαλὼν καὶ ἀποδοκιμάσας πάντα ἑτέρῃ ὁδῷ καὶ ἑτέρῳ σχήματι ἐπιχειρέει ζητέειν, καὶ φήσει τι εἰρηκέναι, ἐξηπάτηται καὶ ἐξαπατᾶται· ἀδύνατον γάρ. (He who, casting aside and rejecting all these methods, essays to find truth by another path and with another method and proclaims that he has discovered something is deceiving and deceived. The thing is impossible.)

IS THE STATISTICAL METHOD EXHAUSTED?

But my candid critic may accept all this and still refuse to recognise the modern statistician as a scientific investigator. He will say: "I am quite prepared to recognise that Graunt and those inspired by him did valuable work. I agree that it *was* necessary both for honest propaganda—for calling attention to the existence of great evils which might be remedied—and even for suggesting fruitful topics of *real* research, that systematic vital statistics should be compiled and published. But in the preparation and interpretation of these statistics, one needs no more than plain good sense. Because the results of their labours are useful, the compilers and analysers of these statistics are no more entitled to rank as scientific investigators than are the equally useful artisans who manufacture our laboratory apparatus. Indeed, when I glance at the pages of acrimonious dispute between rival statisticians touching the scientific claims of different 'coefficients' I am reminded of Sam Johnson's remark: 'Sir, there is no settling the point of precedency between a louse and a flea.'"

Let us consider these two perfectly reasonable contentions: (1) That there is, properly speaking, no special method or art of medical statistics, plain good sense is all that is required; (2) that there is no longer any scope for originality in statistical research, that now, after all these years of tabulation and publication, statistics are on the plane of repetitive semi-skilled manufacture.

THE TERRIBLE RESULTS OF COMMON SENSE.

Is it a fact that a man of good sense can be trusted to interpret statistical data without either special training or (as in Graunt's case) special ability? In 1801 Dr. William Heberden the Younger published "Observations on the Increase and Decrease of Different Diseases." Heberden was something more than a mere man of good sense; he was a scholar, an experienced physician, and had family interest in medico-statistical investigations. His father, one of the most famous of eighteenth century physicians, financed a continuation of Graunt's work by Corbyn Morris. Heberden, then, went over the ground fairly acquainted with his predecessor's work and reached a conclusion which attracted a good deal of attention: he said, "there is scarcely any fact to be collected from the bills of mortality more worthy the attention of physicians than the gradual decline of dysentery." Heberden took together the three titles, bloody flux, colic, and griping in the guts, he showed that the annual average was more than 1000 in the first decade of the eighteenth century, fell to 770, to 700, to 350, 150, 110, 80, 70, 40, and finally 20 in the decade 1790–1800. He attributed this decline to greater cleanliness and better ventilation. But, as Creighton pointed out,[3] Heberden had simply made a statistical mistake; he had supposed "griping in the guts" to be dysentery when it really meant infantile diarrhœa; he made this mistake by overlooking the age-incidence of the deaths assigned to griping in the guts and did not notice that the total had been gradually transferred to the rubric convulsions. He *did* notice that the numbers assigned to convulsions had increased, but explained it by the transfer to this heading of chrisomes and infants, but did not remark (*a*) that transfer had been made already while convulsions were still a small total, (*b*) the gross total of chrisomes and infants was never large enough to make a difference of the required order of magnitude. If you compare Heberden's treatment of this case with Graunt's treatment of the question of whether rickets were a "new disease" in or about 1634, I think you will have no difficulty in deciding that Graunt did have a critical faculty which is really something more than simple good sense, and that a very sensible man like Heberden may blunder badly.

It would be easy enough to mention examples more recent than that of Heberden. Such mistakes look very foolish *when they are pointed out;* but a dozen of them will be made by very intelligent men within a year. I think we may accept the proposition that there is a kind of statistical tact, which is rather more than simple good sense; some are born with it, like Graunt; the rest of us have to acquire it. The second point raised by my objector is worth more consideration.

I wish to consider it under two subdivisions—first, when we confine the scope of the statistical method to what Graunt modestly called his shop arithmetic or to developments of that shop arithmetic which would have been quite intelligible to him; secondly, when we bring into the account a modern calculus which would have been almost as hard for Graunt to understand as it is for many, even laboratory workers, in the twentieth century.

LIFE-TABLES.

I choose as an example under the first heading the case of life-tables. Graunt made the first life-table, and the difference between the last English life-table, with its serried ranks of numerals, and the few figures of Graunt is of detail, very important detail of course, not of principle. A life-table purports to tell us how many of a fictitious population born at the same instant will live, 0, 1, 2, &c., years and has been used for two main purposes. The first, to provide a basis for commercial transactions, to make it possible to buy and sell equitably life annuities, assurances upon lives, and other similar conditional payments; the second to effect a summary and graphic comparison between the states of mortality in different communities or different occupations. In *medical research*, in the sense in which most of this audience understand that term, it has been used by very few. In England, my friend, Dr. John Brownlee,[4] is perhaps the only medical man who has devoted close attention to its possibilities as an instrument of research. I am aware that Bardolph was not thought a good security for Falstaff, so I shall not dwell, as I should like to do, upon the researches of a fellow medical statistician but call a witness from the respectable and unstatistical pages of the *Zeitschrift für Allgemeine Physiologie*. In 1921, August Pütter,[5] of Bonn, published an essay in which he argued that the immense literature dealing with the physiology and pathology of the duration of life, a literature to which such men as Weismann and Rubner have contributed, suffers from the lack of any clear idea as to what really is being investigated. He observes that we know more about the course of life in man than in any other animal, and suggests that it would be just as well to start by learning what there is to be learned from life-tables.

Pütter brings to the subject a fresh mind, and, like an intelligent man, sets his imagination to work to discover a *law* of mortality—i.e., some mental shorthand which will describe the increase of mortality with age. He is interested in the physiological problem of senescence, and so he only considers increasing mortality—i.e., from adult age onwards. As a laboratory worker would naturally do, he first takes the analogy of the destruction of bacteria by a disinfectant and considers the law of decrement which describes that case, the logarithmic law, the expression of the waning of a population opposing a constant power of resistance to a constant force of destruction. He suggests the combination with this of a law of geometrically increasing destructive power, so the law of human mortality he finally reaches is compounded of two factors, (1) which measures a

as a youth; perhaps as candid an account of my present position as unconscious vanity will allow me to make will help others to assess fairly the value of the statistical method.

THE GENERAL CASE AGAINST MEDICAL STATISTICS.

It is generally agreed that statistics of a sort are useful to the medical profession; that, for instance, it is desirable to compute and publish death-rates and records of infectious diseases. But many research workers would deny that data of this kind either ever have been made or ever could be made the subject of a scientific investigation apt to reveal new and important truths, in the sense that the data of experiment can be made to disclose the secrets of nature. Let me try to state the grounds of such an opinion as forcibly as I can.

The medical statistics of any country can, at best, only reflect the opinions of its practitioners of medicine; at worst, they may be a mere translation into figures of the hearsay of laymen, possibly of drunken and venal old women—Graunt's view of the sources of vital statistics in the seventeenth century. Medical statistics between the best and the worst—that is to say, as they are compiled in most civilised countries—record not all the candid opinions of certifying practitioners, but some of their opinions. So long as medical practice is individualistic and death certificates are open to the inspection of the friends of the deceased—as they are in England and Wales—there is some motive to refrain from recording any opinion which may either hurt the credit of the practitioner in the eyes of his clients or do violence to common human sentiments. To subject documents of this order of accuracy to elaborate mathematical manipulation is surely trifling. "How and why did this man die?" is the most tremendous of interrogatories. To answer it fairly and fully may require knowledge and insight which no man has ever had, not Hippocrates, not Sydenham. Our medical statistics are the coding of answers given not by Hippocrates and Sydenham, but by men of only ordinary ability and insight, some ignorant, some biassed. "Dix millions d'ignorances," said Taine, "ne font pas un savoir." No calculus will transmute a million inaccurate verbal statements into an exact numerical appraisement. Can we deduce from this codification of half-truths anything at all which we might not have reached by plain good sense and observation without arithmetic? The Registrar-General tells us that 44,789 persons died of "influenza" in 1919, 112,310 in 1918, and only 7283 in 1917. We needed no statistics to convince us that "influenza" was a great pestilence in 1918, a serious cause of illness in 1919, and relatively unimportant in 1917. The Registrar-General does, indeed, tell us many things we did not know. He says that 29,777 persons were reported to have died of "old age" in 1919, and that four of these ancients were between 45 and 50, 14 between 50 and 55, and 59 between 55 and 60. We also learn from him that "old age" was epidemic in 1909; 33,975 people succumbed to it in that year, but it was much less virulent in 1913 when only 29,801 were cut off. Certainly we did not know these facts until the Registrar-General told us of them; indeed, we do not know them now. Putting it bluntly, what is true in his records is not new to any observant man, and what is new is probably not true. That, I think, is a fair statement of the objections many feel but few express, because, nowadays, statisticians, even medical statisticians, are quite respectable people. Now let us see whether the objection can be met, and met upon ground which is as unfavourable as can well be chosen—viz., the ground of the seventeenth century.

GRAUNT AND SYDENHAM.

Contemporaneously in London in the seventeenth century two men endeavoured to elucidate the natural history of disease. Each used the same figure of speech and supported it with the same authority. The one averred that "The Observations which I happened to make (for I designed them not) upon the Bills of Mortality, have fallen out to be both Political and Natural, some concerning Trade and Government, others concerning the Air, Countries, Seasons, Fruitfulness, Health, Diseases, Longevity, and the proportions between the Sex and Ages of Mankind. All which (because Sir Francis Bacon reckons his Discourses of Life and Death to be Natural History . . . .) I am humbly bold to think Natural History also, and consequently that I am obliged to cast in this small Mite into your great Treasury of that kind."[1] The other, desiderated, "primo Historia, sive morborum omnium descriptio quoad fieri potest graphica et naturalis," and said that, done so that "evitetur censura quam clarissimus Verulamius in nonnullos ejusmodi promissores vibravit," it would be a task not easy of fulfilment.[2]

One of the two was a London tradesman, John Graunt, the other, Thomas Sydenham, *medicus in omne ævum nobilis*. One based his natural history upon tables of figures compiled from the reports of "ancient matrons" whose diagnostic powers were, he thought, affected by the "mist of a cup of Ale and the bribe of a two-groat fee." The other's data were his own careful observations through 20 years of practice in the capital.

Given two men so equipped for the discovery of truth, which was the likelier to find truth, to make known natural historical facts apt to stimulate further research and so lead to further discoveries? Surely the answer is, Sydenham. But if we were to select from the host of natural historical facts of mortality, a fact now trite enough, but a novelty 200 years ago, one fact which has inspired more sanitary effort and more laboratory investigation than perhaps any other, it would be, I think, the enormous excess of mortality in childhood in large cities. One of our two natural historians of disease revealed that fact. He said: "We shall find that about 36 *per centum* of all quick conceptions died before six years old." . . . "When I consider, that in the Country 70 are born for 58 buried, and that before the year 1600 the like happened in London, I considered, whether a city as it becomes more populous, doth not, for that very cause, become more unhealthful: and inclined to believe, that London now is more unhealthful than heretofore; partly for that it is more populous, but chiefly because I have heard, that 60 years ago few Sea Coals were burnt in London, which are now universally used."

These are the words not of Sydenham but of Graunt, and how "the observations which I happened to make" led, directly and immediately, to the foundation of scientific methods of life assurance and, indirectly, to the establishment of those national registers of life and death, without which the work of Simon, of Chadwick, of Buchanan, of Power, and of Shirley Murphy could never have been done, is an oft-told tale. To "the observations which I happened to make" may be traced the inspiration of bacteriological researches carried out by men who never heard the name of Graunt.

What inspiration have modern investigators derived from Sydenham? I do not ask what our debt to him might have been had we been wise enough to invest some of the intellectual money he gave us, but what we *actually* owe, what great discoveries made since the seventeenth century are to be directly traced to Sydenham's inspiration. I think the answer is—none whatever. No great intellect is wasted; Sydenham has, perhaps, a debtor still unborn who will make something of "Epidemic Constitutions."

> "That low man seeks a little thing to do,
>   Sees it and does it;
> This high man, with a great thing to pursue,
>   Dies ere he knows it."

Sydenham was the high man, if you please, and Graunt the low man, but what he sought to do he did do. It is fine to have a soul above mere shop arithmetic, but perhaps unless one does cloak the humanity of one's patients in the guise of mere ciphers and averages, flesh and blood will be too much for us and our interest in the individual happenings

searching out of nature; the equivalent of technique in the mathematical sciences is *notation*, and the history of knowledge has shown that the discovery of a good notation is so important that, with a good notation a second-rate man may go further into the arcana of nature than a first-rate man can penetrate with a bad notation. Now the *notation* of the life-table is exceedingly good. One proof of that assertion is that the notation used in seemingly unrelated cases will help us to discovery. I may be permitted to give a trivial example. During the war there was a good deal of concern over the wastage of labour in munition factories, very wild statements were made as to the numbers of new hands it was necessary to engage in order to maintain a constant strength of workers, and as to the effect of various measures in increasing or diminishing the rate of loss. I was instructed to investigate the subject and thought that one might liken entrance to and exit from a factory to birth and death, and construct factory survival tables formally and notationally analogous to life survival tables.[8] Having once got the idea, its application was simple if laborious, and we not only solved the problem originally proposed—viz., to determine the actual rates of wastage and the effects upon such wastage of changing the environmental conditions—but we were able to show that when, as happened at one time, the output of munitions of a particular type exceeded the demand, there was no need either for dramatic discharges or curtailment of hours, that if merely the industrial birth-rate were reduced to zero by refraining from the engagement of new hands, the population would be reduced to the required dimensions by the operation of the industrial "death-rate" in such-and-such a time. By the application of the life-table method it was quite easy to solve what appeared to be an extremely complicated problem.

This is a trivial illustration; reference to the papers of Prof. W. W. C. Topley[9] suggests far more important applications. This is, indeed, the point to which I have been bringing you by devious paths. I said at the outset that my conception of the statistical method in medicine has changed in the last 20 years; this is especially so with regard to the bearing of statistical method upon experiment. I used to see in the statistician the critic of the laboratory worker; it is a rôle which is gratifying to youthful vanity, for it is so easy to cheat oneself into the belief that the critic has some intellectual superiority over the criticised. I do not think even now that statistical criticism of laboratory investigations is useless, but I attach enormously more value to direct collaboration, the making of statistical experiments, and the permeation of statistical research with the experimental spirit. In this matter Prof. Topley is the pioneer. Topley has endeavoured to study *under laboratory conditions* the genesis and development of epidemics. Down to his time the subject has been examined in absolutely isolated fields. We have had on the one hand historians, public health administrators, statisticians wholly occupied with the records of occurrences of epidemic disease in nature; we have had on the other laboratory workers sedulously investigating the biological properties of the *materies morbi* and searching out the immunological properties of the living tissues of men and other animals. Between these two groups there has been little coöperation, the sanitarians have often drawn on themselves the contempt of the trained laboratory worker by a certain rashness and even amateurishness in their exploitation of laboratory results; the laboratory workers have sometimes displayed an equal crudity in their interpretations of the facts of sanitary history. It has not been recognised that the complex of phenomena in the world of humanity is so vast and the accuracy of the historical record so poor that there is little hope of solving any epidemic problem by the statistical or historical analysis of records alone; there is equally little hope of solving it by the minutely accurate, small scale experiment which has been the fashion of the laboratory worker. We must observe a "population" less complex, less exposed to the play of varied influences than the world of men and women, but much more complex than any laboratory investigator before Topley and the staff of the Rockefeller Institute had dreamed of. But, from the moment that we envisage the possibility of studying an artificial epidemic, we are faced with the need of much greater knowledge of the physiology of the animals we shall use as our material, and of a notation to describe the results.

Topley has worked with populations of mice and has reached such tentative conclusions as these:—

> "We were thus forced to the conclusion that mice, among which an epidemic was spreading, were subjected to an increased risk of death if they were allowed to mingle with normal members of their own species. This conclusion was confirmed by measuring the rate of extinction of a mouse population, among which a given bacterial disease was spreading, according as it was kept in isolation or was subject to a steady immigration of susceptible individuals of the same species. . . . It would seem, then, that the survivors from one epidemic, though in apparent health, are carrying the parasites which caused the disease from which their companions died, and that when they come into contact with any considerable number of susceptible individuals of their own species a process is set up which leads to a fresh outbreak of disease. It seems clear also that these mice which have passed through one epidemic wave are now possessed of some increased powers of resistance to the disease in question, for they tend regularly to outlive the new arrivals in the cage. But this resistance is relative and not absolute, for they tend to die during the later stages of the new epidemic which they themselves have started. . . . We are led to the view that the immigration of healthy but susceptible individuals into a population which has recently emerged from a considerable outbreak of disease is just as dangerous to the community they enter as it is to themselves" (op. cit., pp. 65–68).

Topley reaches these conclusions by treating his data on the lines of a life or survival table; it is evidently the proper way to treat them. Before we can fully profit by experimental studies of epidemics we must learn much more about the course of life, apart from epidemics, in our population. While "laboratory animals" are only used as living culture media or animated test-tubes, people have not bothered about their sociology! In Rössle's[10] vast *referat* on *Wachstum und Altern* one seeks in vain for *any* precise observations of the course of life in animals other than man. He cannot go beyond the cautious conclusion that in such animals as have been "tolerably" (leidlich) studied one finds "a uniform decay of many organs and tissues" rather than a senile central nervous system in a young body (op. cit., p. 569). We have a survival table for one animal other than man—*Drosophila melanogaster!*—made by Prof. Raymond Pearl[11] (*Metron*, 1923, ii., 697).

We know very little of the trend of life in mice. Yet this is important. Prof. Pearl suggests that we can make an exact comparison between the life-table of a fly and the life-table of a human population by merely altering the unit; one year of human life is equated to 1·1279 days in the life of a fly. Suppose we take the common opinion that the average life of a mouse is two years, then a year of human life is equivalent, taking an average human life as 50 years, to about a fortnight, so by that method of reckoning an attack of, say, mouse typhoid ending in recovery is a matter of (humanly speaking) years. We know what a different business, say, a pneumococcal pneumonia is between 40 and 50 and between 20 and 30 from the prognostic standpoint. We have not sufficiently considered the possibility that this factor may be of importance in populations of laboratory animals. We *must* consider this and many other histological factors on statistical lines, with the notation of the life-table and Graunt's shop arithmetic. Such is my answer to the first part of the second question proposed so long ago that you have forgotten it. Using no statistical methods which would not have been intelligible to John Graunt, applying those methods to the controlled populations handled by Topley, it is probable, it is almost certain, that we constantly acting force, his *Vernichtungsfaktor,* (2) the other measures the increasing lability of the tissues and is the *Alternsfaktor*. He shows that the mere arithmetical average called the expectation of life or mean duration of life in any population must be a function of both these factors, but notes that it is only the second which is of importance in the physiological study of senescence. After displaying some arithmetical examples of his proposed formulæ, he writes: "These reflections suffice to make it clear that physiology has no use for the statistical concept of the mean after life-time, but that, on the other hand, from precisely the same data from which statistics draw the concept of a mean after life-time, that is, from the mortality or survival table, physiology can deduce an important concept, the concept of a factor of senescence" (op. cit., p. 25).

As I said at the beginning we are all vain, and it is hard, even for physiologists, to believe that their thoughts had passed through the minds of dead men who were perhaps not even physiologists. Pütter's idea *may* have occurred to de Moivre or one of the Bernouillis (most good statistical ideas have), and it was at least clearly and fully expressed 99 years ago by Benjamin Gompertz[6] who held "it possible that death may be the consequence of two generally coexisting causes; the one chance, without previous disposition to death or deterioration, the other a deterioration, or increased inability to withstand destruction." Gompertz had in mind a law of mortality to express both factors, although he actually proposed one only covering the second—Pütter's *Alternsfaktor*—and a formula, including both a *Vernichtungsfaktor* and an *Alternsfaktor*, was introduced into actuarial practice only 65 years ago by Makeham, and is now termed the Makeham-Gompertz law. It differs in technical detail—for the better—from Pütter's formula, but it seeks to embody precisely the same idea. But although the idea of Pütter, or Gompertz, has been public property for nearly a century, no *physiological* use has been made of it, save by Dr. Brownlee. Dr. Brownlee has pointed out the significance of the formula from the physico-chemical point of view, and made it the basis of reflections which I am too ignorant of physical chemistry to appraise. I have looked at it from a much humbler standing-point. My line of thought was this. Suppose one accepts the suggestion that mortality is fully determined by two factors in Pütter or Gompertz's sense, then are they sufficiently separated by the Gompertz-Makeham "law" for any useful comparison of the strength of the forces at different epochs to be possible? In a general way we know that the environmental conditions of this generation are more favourable than those of our great grandfathers, that many causes of death and illness which were powerful in the eighteenth century are now almost negligible; typhus is extinct, typhoid obsolescent, tuberculosis greatly less fatal than 100 years ago. The death-rate of 1924 will probably not be as much as 50 per cent. of that of 1774. But it does not follow that the natural rate of tissue senescence has changed; that if the environment were perfect men of our generation would live longer than men of the eighteenth century placed under ideal conditions would have lived.

Let us see whether we can test this by the life-table method. The earliest life-table for an English population which is suitable for comparison is that known as the Carlisle table, and was based upon the mortality of part of Carlisle in the years 1779–87; the most recent national table is English Life Table, No. 8, based on the mortality of 1910–12. The Makeham-Gompertz constants of these tables have been calculated, those of the Carlisle table long ago, those for English Life Table, No. 8, by Mr. Trachtenberg,[7] and if we compare the values of the *Vernichtungsfaktoren* in the two tables we find that of the Carlisle table no less than three times as large as that of English Life Table, No. 8. Now let us see how long life would have been under each experience had the *Vernichtungsfaktor* been obliterated. By the nature of the assumed law of senescence, a geometrical rate of increasing destruction. there is no point of age at which *all* will be dead; theoretically some of Mr. Shaw's immortals exist, but we may calculate the age at which the original population will be reduced to one-thousandth or one-millionth, or any desired fraction of its initial number. I find, then, that the age at which only one in a million of those who lived to be 20 would still be alive supposing only the *Alternsfaktor* operative is for the Carlisle experience 105·8 years. For the England and Wales (Makehamised) experience of 1910–12 it is 104·7 years—that is, almost the same. I repeated the experiment on the English Life Table, No. 5, experience of 1881–90 as Makehamised by Mr. Trachtenberg; this table has a *Vernichtungsfaktor* greater by 78 per cent. than that of 1910–12, but the *Alternsfaktor* is again sensibly equal to the others, the one in a million survival age, when the *Vernichtungsfaktor* is abolished is 105·2 years. I made a similar comparison of the national Swedish life-tables for the experiences of 1816–40 and 1901–10 (I obtained the Makeham-Gompertz constants by a rough but sufficiently accurate approximation). The change in the *Vernichtungsfaktor* was not so great, a difference of 21 per cent., but it was considerable, the ages of survival on the stated hypotheses were 104·7 years and 105·5 years. Having reached this point and having further noted the fact that the general run of the *Vernichtungsfakoren* for the Swedish life-tables (eight of which are available) is concordant with the fluctuations of the public health of that country through the nineteenth century, I might be tempted to assert categorically that by a study of life-tables one can (*a*) deduce the quantitative measure of improvement in environmental conditions; (*b*) conclude that the physiological rate of senescence is invariable and that the human span of existence is under no circumstances whatever likely to exceed 110 years. But a little wider induction shows how foolish such a statement would be. Returning again to Mr. Trachtenberg's useful collection of Makehamised tables, we note that although what I have called the *Vernichtungsfaktor* is usually smaller the more favourable the general mortality, it is not always so. Thus he has computed the constants for the 1911–12 experience of London, of the county boroughs, of the urban districts, and of the rural districts. In this series the lowest *Vernichtungsfaktor* is that of London, the highest that of the rural districts, 156 per cent. of the value for London. But London's mortality was not so favourable as that of the rural districts; the mean after life-time at age 20 was 47·08 years on the rural experience, 42·35 years on that of London, and, of course, no sensible person would believe that the general environmental conditions of the rural districts are half as bad again as those of London. There are, at least, two reasons for this discrepancy. The first, that the so-called law only approximates crudely to the description of the natural facts; the second, that we have not got the "facts." These life-tables are not, what some people still seem to think them, records of the way in which men have really died; they are records of the way in which men would have died had they been subjected to conditions to which no real men ever have been simultaneously subjected. The English life-table for the "experience" of 1901–10 does not record the way in which the males of England and Wales died in 1901–10, but the way a hypothetical population would have died out had it been subjected to the *average* forces of mortality prevalent in that epoch. This artefact possibly, indeed probably, does not differ very widely from the truth, only attainable if we had a life card for every person born—a perfectly attainable ideal. But it would not be very sensible to spend much ingenuity in inventing more complex mathematical "laws" of mortality for the sake of representing more closely such data. But even with our crude mathematical hypothesis and our imperfect material we have gained something—viz., a new point of view, and from that new point we see various possibilities of research. Sir Almroth Wright has spoken of the profound importance of a good technique in the searching out of nature; the equivalent of technique in the mathematical sciences is *notation*, and the history of knowledge has shown that the discovery of a good notation is so important that, with a good notation a second-rate man may go further into the arcana of nature than a first-rate man can penetrate with a bad notation. Now the *notation* of the life-table is exceedingly good. One proof of that assertion is that the notation used in seemingly unrelated cases will help us to discovery. I may be permitted to give a trivial example. During the war there was a good deal of concern over the wastage of labour in munition factories, very wild statements were made as to the numbers of new hands it was necessary to engage in order to maintain a constant strength of workers, and as to the effect of various measures in increasing or diminishing the rate of loss. I was instructed to investigate the subject and thought that one might liken entrance to and exit from a factory to birth and death, and construct factory survival tables formally and notationally analogous to life survival tables.[8] Having once got the idea, its application was simple if laborious, and we not only solved the problem originally proposed—viz., to determine the actual rates of wastage and the effects upon such wastage of changing the environmental conditions—but we were able to show that when, as happened at one time, the output of munitions of a particular type exceeded the demand, there was no need either for dramatic discharges or curtailment of hours, that if merely the industrial birth-rate were reduced to zero by refraining from the engagement of new hands, the population would be reduced to the required dimensions by the operation of the industrial "death-rate" in such-and-such a time. By the application of the life-table method it was quite easy to solve what appeared to be an extremely complicated problem.
